ERP: Enterprise Resource System, encompasses the whole of internal processes in the enterprise, for example, finance accounting, controlling, purchases, production, distribution.

Industry 4.0: Trend towards automation and data exchange in manufacturing technologies and processes. It encompasses the internet of things (IoT), cyber-physical systems (CPS), artificial intelligence

(AI), cloud computing and cognitive computing. A concept related to RTE, in the field of data processing in real time and the fastest possible business processes

MES: Manufacturing Execution System, IT system which provides information needed for optimization of production activities.

Real Time: Receiving and processing of source data by the system immediately at the time of their creation

RTE: Real Time Enterprise, enterprise which processes information in real time.

SCADA: System Control And Data Acquisition, IT system which serves for visualization, supervision and control of complicated technological lines, industrial processes, machines and equipment.

SCM: Supply Chain Management, IT system which encompasses all activities related to flow of goods and services.

Smart Factory: Manufacturing based on computer-integrated manufacturing, interoperable systems, digital information technology, high levels of adaptability and rapid design changes (f.e. on demand), optimization of the supply chain.

Interfacing Communication and ICTs in a Divisionalised Structure: Effects on Good Governance

Toyosi Olugbenga Samson Owolabi

Ekiti State University, Nigeria

INTRODUCTION

Every organization exists to achieve some set goals. To facilitate quick and cost effective attainment of these goals, they are broken down into different tasks for different people to undertake. Jobs are grouped into departments such as marketing, sales, advertising and manufacturing depending on the size of the organisation. In such a corporate setting, there must be constant communication and information sharing to properly harmonise the activities of each department. Information and communication technology plays critical roles in fast-tracking organizational decision making process. The more progress the companies make, the more they can contribute to national development. Against the backdrop, this study, anchored on technological determinism and governance theories, evaluates the interface of communication and ICTs in a divisionalized organisational structure and the implications on corporate governance and sustainable development in Nigeria. The chapter also attempts to provide good understanding of the concept of divisionalised structure, pinpointing its features, purposes, prospects and challenges. The study also seeks to identify the role of communication and ICT in the organizational decision making process.

BACKGROUND

The quests for sound organizational management and efficient corporate governance have received more impetus in today's business environment. This is because it has been observed especially among large scale enterprises and multinational companies of incidences of wastage of human and material resources, inefficiency and sluggishness in the corporate decision making process at huge cost to the company on one hand and to shareholders on the other. In contemporary corporate setting, large scale organisations tend to have more specialisation, departmentalisation, centralisation and regulation than small scale enterprises. Particularly, companies with wide variety of products often give preference to divisionalisation purposely to ensure efficiency and effectiveness in the corporate decision making process. However, despite the adoption of divisionalised structure supported with effective communication and information technology, there are yet apprehensions that such practices oftentimes do not translate to good corporate governance characterised by growth, probity, accountability and return on investment. To build sound business management founded on good corporate governance that will guarantee sustainable development in Nigeria, there are tasks that must be accomplished.

DOI: 10.4018/978-1-7998-3473-1.ch044

According to Gbadamosi and Adebakin, (2006), organisations exist in a society and combine materials (technology) and human (personnel) resources for the attainment of corporate survival. The earlier conception of organizations described them as highly structured, hierarchical, restrictive and undemocratic ((Eisenberg and Goodall, 1993). Miller (1995) cited by Soola and Ayoade (2000, p.10) has characterized organizations using three different features. First, an organization includes two or more people who are seen as social collectivities that require some level of understanding, coordination and communication to act in concert. Second, an organization is structured in the pursuit of a goal or set of goals which direct the activities of the organization members and are equated with the purpose and goals of its members. Third, an organization involves coordination of activities which is a process by which organizational goals are achieved. Although organisations have been defined in various ways by different theorists, virtually all the definitions contained certain common features which Adolor (1985, p.63) summarised as follow:

- an interdependence, or interlocking activities;
- role specifications for members who occupy positions;
- a division of labour and varying degrees of job specification;
- status hierarchy which exists as a coordinating and controlling mechanism;
- a dynamic system which is in a constant state of change;
- a system of processing various 'inputs' to produce various 'output';
- a communication network, or more accurately, a network of networks, and;
- a combination of individuals and groups- a group of people.

Modern society depends largely on the efficiency and optimal performances of its organisations for its social and economic sustenance. Business organisations such as manufacturing, aviation, banks, insurance, petroleum and gas, construction and media among others, thrive in an environment of sound management. As a process, management can be defined as network of activities, which entail responsibility for the effective and economic planning and regulations of a business enterprise. Going by the above definition, management process involves goal setting, planning and implementation, measurement of outcome and general supervision.

It is important to note that as business manager in any corporate setting, responsibility demands that one must be accountable. Accountability is a function of responsibility. According to Glautier et al (2011), specific responsibility arises by reason of the nature of a relationship either patented or contractual responsibility. The pre-condition to good accounting system is the presence of responsibility towards others which imposes an obligation to account for one's actions. Responsibility accounting is a basic component of management functions and control systems particularly in large organizations with product or service diversification (Arora (2012). Accounting involves the process of identifying, measuring, recording, reporting and communicating economic information that permit judgment and sound decision making by the end users. It also includes keeping accounting records, data, information and reports, monitoring cash position and settling of bills as at when due.

As the subject matter of accounting is very important in the day to day organizational management so also is the issue of communication, which is a major prerequisite towards managerial accountability as well as achieving the overall organizational goals and objectives. In addition, for every person working in a particular establishment, there is the necessity of interacting and functioning together to accomplish corporate goals. In order to facilitate interrelationship in organizational setting, communication is a key factor (Gbadamosi and Adebakin, 2006).

For communication to achieve its purpose, both the sender and receiver must have shared code otherwise, there would be no intelligibility and information could get lost. In today's corporate environment, managers desire information about their organization and its operational environment at a faster rate than before. This, according to Koontz and Weihrich (2004), is because a slight hitch in the production line can result in huge losses to the organization. Therefore, to accelerate free flow of needed information for efficient business management, information and communication technology ICT provides a variety of proven tools and techniques that can fast-track every facet of organizational communication and management process.

Figure 1. Diagram showing communication as a process

Each organization decides to choose the appropriate structure that fits its policy. The structure of an organization refers to the different hierarchies and levels that can drive the company to accomplish set goals. Organizational structures range from simple to complex but basically, there are three types: functional, divisional and matrix structure. The adoption of a particular structure depends on so many factors such as the nature of business, sector, product mix, size of the organization, personnel, management style, geographical location and spread, corporate vision and mission, strategic business direction among others (Kozenkow, 2015).

Top management of growing and large business organisations are daily confronted with the challenges of effectively managing business tasks, activities and responsibilities to achieve their corporate objectives. This explains why modern organizational practice is dynamic and gives preference to constant structuring and restructuring so as to guarantee efficient management system that conforms to international best practices.

Some scholars have proffered different conceptual definitions of organizational structure, which they viewed as the ways in which responsibility and power are allocated and work procedures are carried out by organizational members (Dewar & Werbel, 1979; Germain, 1996). There are body of evidences showing that the size of an organisation affects its structure. For instance, large scale organisation tends to have specialised, departmentalised, centralised and regulated structure. This usually facilitates formal allocation of job schedule and administrative mechanism to control and integrate work activities in order to guarantee efficiency.

Understanding the Concept of Divisionalisation

The basic philosophy of divisionalised structure is that it might be difficult and problematic to centrally managed large diversified organisations as a single entity hence the rationale or necessity of decentralising into divisions along functions, product and territorial lines (Oliveira & Takahashi, 2012). Other reasons may be due to target customers and raw materials. Moreover, divergent laws, customs or culture or regulatory framework of different geographical region may demand that an organisation adopts the policy of divisionalisation to fully realize its corporate objectives. Ogundele (2012, p.24) identified seven structure which include (i) entrepreneurial structure (ii) mechanistic structure (iii) professional structure (iv) diversified structure (v) innovative structure and (vi) political structure.

While contributing to the discourse on organisational segmentation, Dury & El Shishini (2005) describes the division as profit centre or investment centre, subsidiary or business unit or branch of a corporate body. “A division is a part of the organisation where the manager is accountable for generating revenues, controlling costs and making satisfactory return on capital invested in the division.” Whatever name it is called whether a subsidiary, department or division, the important thing is that divisionalised structure involves the establishment of separate or semi-autonomous units on the basis of individual products, product groupings, functions or geographical operations. Contrary to departments, divisions are more independent, with each having its top executive and management to handle their own hiring, budgeting, accounting and finance. In effect, it gives room for decentralised decision making process of an organisation. In most cases, divisionalised model is commonly adopted by all large, thriving multinational companies like General Motors, General Electric, IBM, Microsoft, Nestle, Unilever, Cadbury and many other such conglomerates around the world.

Figure 2. Diagram showing divisional organisational structure

Organisation may also be departmentalised according to functionality. Functional structure simply means having all activities of a similar kind within an organisation like production, engineering, personnel, purchases, sales or marketing and finance under a departmental head. Alternatively, big organisations may operate a divisionalised structure based on their products where the divisional head is responsible for all operations, revenue generation and cost management.

Responsibilities of Central Management and Divisional Managers

In a divisionalised structure, the top management team are duty-bound to carry out certain roles. These comprise: determining the strategic direction of the organisation in terms of vision, mission, core values

and culture, formulating the corporate goals for the organisation, evaluating and approving division's business plan, periodic performance assessment and monitoring of division's activities, appointment, dismissal and promotion of divisional managers, providing support services like financial, human resource, corporate and legal services.

The divisional managers on the other hand are expected to manage and implement divisional business plan and regularly provide divisional reports for the central management.

Benefits of Divisionalisation

When an organisation creates organisational structure into divisions, there are inherent benefits. According to Ogundele (2012, p.14), it facilitates quick and easy decision making process, assists the top management in evaluating both personnel and product performances, allows divisional management to operate freely and independently, enables the management and the divisional managers to collaborate and achieve managerial goals and provides opportunity for career development leading to easy realisation of management succession plan. Other benefits include enabling effective delegation of responsibility and determination of product performance and contribution to organisation's profit margin.

Limitation of Divisionalised Structure

Studies have shown that despite the attractiveness of divisionalised structure, there are inherent risks in this management practice. Although it is a better alternative for large scale enterprises and bureaucratic organisational structure yet, it is a very complex and complicated practice that would require good understanding and knowledge to implement. Most importantly, there is the likely problem of improper and inadequate coordination and control system which may result in conflict of interest between the central management and divisional managers. Oftentimes, if this situation is not properly managed, it can degenerate into crisis that can undermine the entire system. Among others, divisionalised structure may lead to escalated cost of management, frustration of central management if divisional managers keep vital information from them, divisional managers may misuse delegated authority for self-enrichment and management might lose control of the divisions, if effective monitoring mechanism is lacking (Hall & Tolbert, 2009, p.213).

Theoretical Foundation For better grounding of this paper, it is premised on two theories; technological determinism theory and corporate governance theory.

Technological Determinism Theory

This theory propounded by Everett Rogers in (1986) is one of the intellectual constructs that interprets and provides the direction for this paper. The term 'technological determinism' was coined by Thorstein Veblen and it revolves around the proposition that technology in any given society defines its nature. Technology is perceived as the driving force of culture and history in a society. It explains who or what could exercise control over human affairs. The theory questions the degree to which human thought or action is influenced by technological factors.

According to technological determinists, particular technical developments, communications technologies or media are the sole or prime causes of changes in the society. Technology is seen as the fundamental condition underlying the pattern of social organization (Chandler, 2014). The first major elaboration of a technological determinist view of socioeconomic development came from Karl Marx. His

perception of the theory is that changes in technology and specifically productive technology, constitute the primary influence on human social relations and organizational structure, and that social relations and cultural practices ultimately revolve around the technological and economic base of a given society. Marx's position has come to be accepted in modern society, where different kinds of technological innovations have altered man's life and its environment. This can be seen in the accelerated pace at which roles are performed and how technological advancement in-turn influenced the cultural, political and economic aspects of the society.

Technological determinism theorists such as McLuhan believe that the advancement in technology especially in the area of information and communication ICT has constricted the world into a global village through reduction in distance, time and space. In other words, information technology has transformed the world into a globalised village where ideas and culture are frequently exchanged. In addition, the theory believes that new technologies have strong potential of influencing human five senses and his entire existence.

Corporate Governance Theories

Although there are so many corporate governance theories, however, for this paper, we are going to dwell on 'agency' and 'stakeholders.'

Corporate Governance Theories

Although there are so many corporate governance theories, notwithstanding for this paper, we are going to dwell on agency and stakeholders.

Agency Theory: According to this theory, corporate governance believes there must be separation between the ownership of an organisation and employees which results in principal-agent relationships otherwise referred to as employer-employees relationships in modern corporations. The agency theorists regarded corporate governance as a mechanism where a board of directors is a crucial monitoring device to minimize the problems brought about by the principal-agent relationship.

Two key factors according to the theorists were observed to be responsible for agency theory. According to Daily, Dalton and Cannella, (2003), the first factor is the reduction of corporation into two major participants, shareholders and managers whose positions and interests are clear and distinct. The second assumption is that humans are self-interested and reluctant to sacrifice their personal interests for the interests of the others. An organisation, public or privately owned as a legal entity is seen as a connection of different interests all of which have come to equilibrium within the framework of contractual relationship among the stakeholders. These contractual relationships, according to Jensen and Meckling (1976), are not only with employees, but with suppliers, customers and creditors. The motive of this contractual relationship is that each party to the contract has the responsibility to maximize the value of the organization, reducing the agency costs so as to sustain the organisation. The agency theory is of the notion that the principals have the obligatory role of monitoring the corporate activities. In this regard, they or their agents who oftentimes constitute the members of the Board of Directors performs governance function in serving the shareholders by ratifying the decisions made by the managers and monitoring the implementation of those decisions in order to shore up the share value of the company. In cases where the principal fails to monitor the activities of the agents (managers), the agency theorists believe there is the tendency that the managers may sometimes fail to maximise the shareholders wealth in order to satisfy self. This is where the role of accounting becomes relevant in reducing the agency

cost in an organization. This can be achieved effectively through written contracts tied to the accounting systems as a crucial component of corporate governance structures. The understanding is that if a manager is rewarded for their performance through the accounting profits, they will attempt to increase profits which will lead to an increase in bonus or remuneration resulting from profit increase.

The agency model assumes that individuals have access to complete information and investors possess significant knowledge of whether or not governance activities conform to their preferences and the board has knowledge of investors' preferences (Smallman, 2004). Therefore according to the view of the agency theorists, an efficient market is considered a solution to mitigate the agency problem, which includes an efficient market for corporate control, management labour and corporate information (Clarke, 2004).

Stakeholders' theory: This theory centres on the issues concerning the stakeholders in an institution. It postulates that a corporate entity always seeks to maintain a balance between the interests of its diverse stakeholders in order to ensure that each interest of constituency receives some degree of satisfaction (Abrams, 1951).

Stakeholder theory identifies the parties involved apart from investors, employers, suppliers and customers include governmental bodies, political groups, trade associations, trade unions, communities, associated corporations, prospective employees and the general public. In some scenarios competitors and prospective clients can be regarded as stakeholders to help improve business efficiency in the market place. Besides, stakeholder theory has also recognized that the activities of a corporate entity affect the external. This means, the organisation is also accountable to some external publics as well as to stakeholders. It has however been argued that the performance of a firm is not and should not be measured only by gains to its stakeholders. Other key issues such as flow of information from the management to lower ranks, interpersonal relations, working environment among others are all critical issues that should be considered (Jensen, 2001). The three identified theories above have been found to possess the customized principles and experience that explain the role of communication and ICT in ensuring managerial accountability and optimal business profitability in a divisionalised structure, and by extension how it serves to impact on general corporate governance and sustainable development.

Communication, ICTs and Divisionalised Structure: A Trinitarian Interaction

In order to ensure managerial effectiveness, managers in every organisational division need pertinent information that can assist them to take informed decision. According to Okwechime (2015), communication is the transmission of information from one party to another through the use of symbols within the frame of reference of both parties (Soola, 2008). Communication cannot be regarded as effective unless the message transmitted is clearly and unambiguously understood by the receiver who must respond to the content. In organisational communication, (Gbadamosi and Adebakin, 2006, p131-2) identified seven forms that communication can take. These include

- giving instruction;
- sending and/or receiving information;
- exchanging idea;
- announcing plans or strategies;
- comparison of actual result against a plan;
- laying down rules or procedures;
- job description and organisational chart

Giving the different stakeholders involved in organisational setting therefore, information is usually communicated in various directions: vertically, horizontally and diagonally.

Figure 3. Diagram showing communication flow

Vertical Communication

This type of communication flows from people at higher level of organisational organogram to those at the lower rung, in other words, superior to subordinate. It is also referred to as downward communication. This kind of communication could be oral such as face-to-face instructions, speeches, meetings, telephone, instant text messages, grapevine and public address system PAS. It could also be written such as memos, organisational handbook, employee manuals, faxes, telegrams, proposal, contract, postcard, advertisement, brochure, news releases, magazine, letters, pamphlet, policy statement, internet websites, and electronic news displays (Koontz and Weihrich, 2004, 327).

Upward Communication

This also flows from subordinate to the superior. However, this type of information flow often encounters gate-keeping at different points by the superiors along the communication chains who may find the entire message or a part of it unpleasant. Thus, the entire message or a part of it may be filtered out deliberately. Notwithstanding, it needs be emphasised that the managers constantly require objective transmission of information for decision making process. The management needs information on daily production performance, marketing facts, and financial data among others. Koontz and Weihrich, (2004, p.327) also identified the media used for horizontal or upward communication to include: suggestion systems, appeal and grievance procedures, complaint systems, counselling sessions, joint setting of objectives, the grapevine, group meetings, practice of open door policy, morale questionnaires, exit interviews and the ombudsperson.

Horizontal Communication

This type of communication occurs when information flows between the people on the same rank in the same section or department or in different section or department.

Lateral Communication

This occurs among persons at different levels of different departments who have no direct reporting relationships with one another. This is also referred to as diagonal or sideways communication.

External Communication

This is otherwise regarded as corporate communication. Organisations do communicate regularly with their external stakeholders so as to establish and guarantee mutual understanding, acceptance and cooperation. The responsibility for information sharing to both internal and external publics falls within the ambit of corporate communication function. To effectively reach the heterogeneous audiences (publics) spread across the nation as large as Nigeria and beyond, there must be active partnership between the organisation and the mass media. The public relations department needs the traditional media (prints and electronics), new media (social media) and the indigenous media to transmit information to its numerous publics.

Role of ICTs in Organisational Decision making process

In this era of information and communication explosion vividly illustrated by rapid evolution of new technologies in the areas of computer and internet, ICTs have impacted greatly not only on information gathering, processing and dissemination within and outside the organisation but on the decision making process. Organisational managers are daily inundated with the art of making decision. The choices and how well the decisions are made determine the future sustainability of the company. Making decision is one of the most significant activities in a business environment on which, the advent of ICT has had profound influence. According to Ramey (2015), ICT simplifies and accelerates the decision making process by providing an organisation with a decision support system (DSS) and artificial intelligence (AI) system. The combination of these ICT systems helps a business to generate information through online analytical process (OLAP) and to facilitate decision making tasks that might require significant effort and analysis.

Decision making process as an important area of business management has also been researched to investigate the influence of ICT in different industries, with particular emphasis on strategic decision making (Dika, 2004). There are different types of decisions. First, straightforward decisions, which are known as programmed decisions, or decisions that occur frequently enough that we develop an automated response to them. Decision could also be non-programmed. In other words, this is a unique and important decision that requires conscious thinking, information gathering, and careful consideration of alternatives. A crisis situation constitutes a non-programmed decision for organizations (Qureshi, et al (2014). A classical example was when DE United Food Industries Ltd, the maker of indomie noodles, the most popular fast food among Nigerian school pupils was alleged to have produced and sold contaminated product to the market. Headlines such as “How Indomie Was Contaminated”; “Nigeria: NAFDAC Recalls killer Indomie for Destruction” and “Management of “Killer” Indomie Scare and Impact on Consumer” among others were seen on the pages of Newspapers.

The popular product’s image received another bashing when rumours made the rounds that some unidentified persons had died after taking meals of Indomie. Within few hours when the news broke, unknown persons had begun sending text messages spreading the unsavoury message about Indomie

to Nigerians living in different parts of the country. The story which appeared in the front pages of all the national newspapers gave the management of the company sleepless nights for about two weeks.

Apart from programmed and non-programmed, decision making can also be classified into three categories based on the level at which they occur. 'Strategic decisions' set the course of an organization; 'tactical decisions' are decisions about how things will get done while operational decisions refer to decisions that employees make each day to make the organization run

Decision making involves various processes which are influenced by technology. As can be seen in the diagram below, there are eight interconnected steps in organisational decision making process.

Figure 4. Steps in Decision-Making Model

When trying to make crucial decision, there is dedicated software that can enhance the process. These, according to Ramsey, (2014, p.14), include:

- Decision support systems (DSS) – This is a highly flexible and interactive IT system that is designed to support decision making when the problem is not structured.
- Group decision support system (GDSS) – This is a type of decision support system that facilitates the formulation of and solution to problems by a team.
- Geographical information systems (GIS) – This is a decision support system designed specifically to work with spatial information.

- Artificial intelligence (AI) – the science of making machines imitates human thinking and behaviour.
- Expert systems – This is an artificial intelligence system that applies reasoning capabilities to reach a conclusion.
- Neural network – This is an intelligence system which is capable of learning to differentiate patterns.
- Genetic algorithm – This an artificial intelligence system that mimics the evolutionary, survival-of-the-fittest process to generate increasingly better solutions to a problem.

Transaction Processing System(TPS) ‘processes thousands of routine transactions that occur every day in most organizations, including sales, payments made and received, inventory shipped and received, and employees payroll (Bioney, 2000:35)

Management Information Systems (MIS) Computer systems used by Tactical management (middle managers) provide information in the form of reports and displays to managers and many professionals. For example, sales managers may use their networked computers and web browsers to obtain the daily sales volume of their products and access the company’s intranet for their daily sales analysis reports in order to evaluate the performances of each sales representative The MIS is also believed to have the potential of solving many other problems such as poor program scheduling, poor estimate of staff requirements, and lack of accurate information on personnel and facilities, piling-up of administrative matters, lack of feasible budget estimates among others (Fabunmi, 2003).

Executive Information systems (EIS) These systems provide critical information from a wide variety of internal and external sources in easy-to-use displays to executives and managers. The top management and divisional managers need constant supply of information so as to take rational decisions that can uplift the fortune of their organisation. This, they can easily glean through the internet technology.

While emphasising the importance of ICT in organization and manpower development, Reffell and Whitworth (2002) cited in Owolabi (2018) note that skills in book keeping, secretarial service, clerical and administrative work, spreadsheets, word processing and databases, stock taking, reprographics, information gathering and storage, photography and graphic design among others constitute a set of computerized services that necessitate ICT skills.

E-mail has become one of the predominant forms of communication employed internally and externally. Internally it has replaced print materials such as newsletter, memos and face to face communication and externally, it has replaced news releases, and media alerts among others. The cell phone has added a new dimension to how information and messages are communicated. Within the cell phone, communication platforms such as facebook, twitter, instagram, whatsapp among others are used to send instant and short messages to targeted public. Web logs or blogs and web site are online platforms where organisations can share information with their stakeholders. Many organisations have also created intranets (internal internets) and extranets (external internets) used to share large volume of information with their employees, journalists, investors and consumers. Podcasting, live telecast through television and live streaming through the instrumentality of ICTs have added new angle to information dissemination, news sharing and special events.

Recognising the cross cutting nature of Information, Communication and Technology and their roles in the social and economic development, OECD (2002) and Michalsons (2018) assert that ICTs are primarily intended for the recording and/or processing, monitoring and transmission of voice, data, image, text or any combination used in the following activities: accounting, calculating, data processing, data transmission, duplicating, text processing, document reproduction, document transmission, record

keeping and record retrieval, broadcasting or transmission for entertainment or information purposes of voice and/or text or any combination thereof and/or; the provision of services relating to the above.

ICT has not only brought about fundamental changes to communication process, organisations can now respond faster to global changes. ICT has started changing the way businesses are done and create new value. Business transactions are now made possible electronically as people can produce and buy goods and services online (Shafer, 2000). Apart from heightening the production and distribution of goods and services, ICT also improves competition and innovation among the divisional groups as well as in the global market (Koontz & Weihrich, 2004).

The organisation structures for the global economic and business environment vary in many ways. There is no best way to structure; the most important thing is for each organisation to choose the most suitable pattern based on prevailing factors. Divisionalised structure which is the focus of this paper has its advantages and disadvantages. Notwithstanding, a company may internationalise its operation by simply establishing its headquarters and the company may in the course of time expands its operations, foreign subsidiaries and international divisions in various countries and regional block such as Africa, Asia, Europe among others. In addition, African division may be divided into Southern, Western, Northern and Eastern countries with each reporting to a manager in charge of global operation at the headquarters. Whatever the structure, one thing is constant. No division is completely independent of others. They are connected and each division is supervised through information and communication technology.

Communicating Corporate Governance for Sustainable Development

The economic growth and the socio-economic development of a nation are predicated upon the policies and programme put in place by the political class. Whatever the economic policies initiated, it is the responsibility of the business organisations to translate them into tangible products and services that determine the Gross Domestic Product (GDP) of the nation (Oboh, 2004).

Globally, the international community particularly, the World Bank and UNESCO have continued to show concern about the unenviable economic condition of the developing world as vividly illustrated by socio-economic instability, heightened inflationary trend and corrupt practices such as stealing, money laundering, round-tripping among others. In most cases, poverty, diseases, unemployment and underdevelopment are widespread where these indices are paramount. The reason was that, the funds that should have strengthened the economy oftentimes found their ways into private offshore accounts domiciled in another country while leaving the home country's economy gasping for breath. For example in Nigeria, many large organisations that were once thriving well in Nigeria have wound up operation or are presently struggling to survive due to factors that borders on lack of sound financial management and bad corporate governance.

The success or otherwise of any organisation is predicated upon the quality of governance put in place. This means, governance is a determining factor of the quality of decision made to solve organisational problems. According to Carrington, DeBuse, and Lee (2008), within the context of international organizations, "governance describes the processes and institutions that guide and restrain the collective activities taken by an organization and its stakeholders".

Against the backdrop, corporate governance therefore, is a process by which business associations are directed and controlled. While contributing to the corporate governance discourse, Esty, (2007, p.36) observes that the concept as it applies to business organizations has three characteristics: first, a shared understanding of objectives and standards of conduct pertinent to the organization's specific subject or goal of governance; second, agreed-upon rules that seek to give structure and substance to the organization's

objectives; and third, a regulatory structure to monitor and enforce compliance with the organization's rules, amend and resolve disputes arising from their interpretation. Against the observed characteristics, three pertinent things are evident in a good governance system whether private or public. These include: an agreed condition that must be fulfilled by stakeholders in the organisation; every stakeholder is bound by standing rules that serve as code of conduct while seeking to accomplish corporate goals and a governing body that ensures interactivities of every department of the organisation. To guarantee workable agreement to work together under a common authority for the purpose of achieving a stated goal there must be mutual understanding. This is where communication becomes germane. The personality of the people who constitute the governing body determines the extent to which information is shared among the stakeholders. According to Jeremy (1966, p.16), "Information is power. Without it, there can be no accountability. The more people who possess it, the more power are distributed". At this point, the mass media become very relevant to serve as efficient watchdog over the management and conduct of both public and corporate affairs. According to the normative theories of the press, the media enjoy certain freedom in the society which is expected to make them socially responsible to the society. "The mass media serve the economic system by connecting manufacturers/service providers with sellers, performing surveillance role; and by giving priority in coverage to economic content and development needs of the society" (McQuail 2010). The media's responsibility as the nation's watchdog is to clearly ferret out every underhand deals among the political and business groups as well as bringing to light and analyse harmful behaviours among the citizens which are capable of compromising the ideal corporate principles and constitute potential threat to development.

The issue of underdevelopment has since the beginning of this millennium gained serious attention from the international community. The outcome of the year 2000 United Nations summit was the eight interdependent development goals otherwise referred to as Millennium Development Goals, (MDGs) (Frank, 2008). This was again reviewed in year 2015 summit to 17 goals now known as Sustainable Development Goals (SDGs) (UNDP, 2015, p.4). In modern society, professionals have all agreed that communicating useful and applicable information in a corporate setting through vibrant (ICTs) is foundational to sustainable development.

Oladipo (1996, p.1) cited by Owolabi (2014, p.101) defines sustainable development as:

"development that not only generates economic growth but distributes its benefits equitably; empowers people rather than marginalising them; it gives priority to the poor, enlarging their choices and opportunities and provides for their participation in taking decisions affecting them. It is a development that is pro-poor, pro-nature, pro-jobs, pro-women and pro-children."

Owolabi, (2018) emphasizes that Nigerian corporate body has not actively participated and benefitted maximally in the globalized market due to lack of vibrant information sharing channels. This explains Olubamise's (2010) assertion that significant progress in virtually all areas of human endeavours including global communications, trade, business, culture, education, services, entertainment, tourism and research can only be guaranteed in an environment where ICTs are given a pride of place. According to Koontz and Weihrich (2004, p.372), effective communication supported by ICT among others, "increases outputs in the production and distribution of goods and services; intensifies productivity which in-turn results in higher living standards; improves global impacts, enhances competition and innovation which are made possible by processing large amount of data in research and development."

CONCLUSION

The performance of divisionalised companies can be measured by return on investment or residual income. This can also be assessed by evaluating the organisational contribution to the globalisation process. However, it is observed that globalisation has placed some nations, including Nigeria at economically disadvantage because they lack the basic requirements that can guarantee their active participation with other globalising nations. According to Ihonvbere (2002, p.67), these requirements include “growing economy, effective communication and functional ICTs, highly trained technical manpower and supportive institutional capacity and good governance exemplified by transparency, openness and accountability”. The government of Nigeria in particular needs to invest more in ICT (hardware and software) and manpower development as well as diversifying the economy for better participation in the globalization process.

Divisionalised structure according to territory, product or service has been observed to be a very good model of organisational departmentation among growing firms. However, it has been perceived that there is the need for efficient communication among the stakeholders who are affected by the organisation and whose activities can affect the organisation. The quantity and quality of information shared among this various categories of stakeholders will define their relationship with the company and its ultimate success or otherwise.

KEY TERMS AND DEFINITIONS

Corporate Governance: This is the distribution of resources, rights and responsibilities among different participants in the corporation and description of the rules and procedures governing decision making on corporate affairs.

Decision Making: It is an organisational concept referring to making choices among alternative courses of action.

Divisionalised Structure: Is defined as a segment within the organisation where the divisional Chief executive officer is responsible for most of the production and marketing activities of the segment and is accountable for profitability measure.

Information and Communications Technology (ICT): Is an umbrella term that includes any communication device or application, encompassing: radio, television, cellular phones, computer and network hardware and software, satellite systems among others, as well as the various services and applications associated with them, such as video conferencing and distance learning.

Organisation: Is a group of people who are seen as social collectivities that require some level of understanding, coordination and communication to act in concert.

Organisational Communication: For management purposes, communication is perceived as the process by which people working in organisations transmit information to one another and share meanings.

Responsibility Accounting: Is defined as a method of accumulating and reporting both budgeted and actual costs as well as raising the level of revenues by divisional managers saddled with the responsibility.

Information Technology in Mining Services Applications

4

Pankaj Kumar Mishra

CSIR-Central Institute of Mining and Fuel Research, Dhanbad, India

1. INTRODUCTION

Information technology (IT) can play a significant role in mining industries by driving continual improvements in efficiency and safety, reducing the cost of extraction of coal and minerals and maximizing profits. Mining, being hazardous in nature, is one of the oldest and most important industries (Agricola & Hoover, 1950). Coal and minerals extracted from mining industries always take part in driving growth and steering progress across various aspects of the economy of the nation. Energy is collectively acknowledged as one of the most significant contributions for economic growth and human development (Dialogues at the Economic and Social Council, 2008). The growth of the nation, taking into account the all segments of the economy and all sections of society, is dependent on meeting its energy requirement adequately. Coal is the most important component of energy matrix for a long time and still contributing a reasonable amount of energy supply to the nations (Yuan et al., 2018; Melikoglu, 2017; Tiewsoh, Sivek, & Jirásek, 2017; Garg, 2012). On the other hand, minerals are important contributors for the production of metals/alloys, fertilizers, ceramics, electronic items and an extensive range of other products (Rankin, 2011). It is worth mentioning that business existence in the present scenario is dependent upon the ability of the management to update with real-time information, make decisions and execute timely. Now the question arises, how to do it? The answer is the adoption of information practices and automated technology. Further, in order to stand parallel in the market with other industries, the mining including oil and gas industries is also taking up the state-of-the-art technology in its operations. Mine safety is in general based on the use of geotechnical and environmental information to make suitable and timely decisions in order to prevent hazards. The continuous involvement of IT applications in mining industry can i) improve the mechanism of information dissemination, ii) enhance safety, iii) provide remote operations and excel towards mechanization, iv) improve fleet management, v) analyze environmental impact of mining operations, vi) map the exploration data and estimate the ore reserves, vii) improve the approach from material extraction and marketing to sales and transportation and viii) overall increase efficiency to improve productivity, reduce cost of production and maximize profits. On the other hand, in the oil and gas sectors, information technology helps to optimize the processes and simultaneously enhances the efficiency of upstream and downstream operations (Anthony and Abdulkareem, 2013; Petersen, Doyle, Carlsen, van der Linden, Myhre, Sansom, Skavhaug, Mikkelsen and Sjong, 2008)

2. BACKGROUND

Earlier researchers have developed and even proposed a number of IT based systems for improving the overall efficiency of mining operations. Golosinski (2001) recapitulated the IT-related developments and their impacts on the mining industry. Further, Chaulya, Bandyopadhyay, & Mishra (2008) proposed

DOI: 10.4018/978-1-7998-3473-1.ch045

futuristic development of IT-based systems by highlighting the existing problems and their respective solutions by proposing a web-based information and decision support system for coal mining industry. Gupta, Mukerjee, & Singh (2013) presented various scopes of application of IT for the Indian mining industry. A comparison between traditional and modern design techniques of mining methods using computer and IT has been illustrated by Miladinović, Čebašek, & Gojković, (2011). A number of applications of Radio Frequency Identification (RFID) as well as wireless sensor network (WSN) for information dissemination including tracking and tracing of miners, equipment and explosives have been discussed for mining sector (Bandyopadhyay, Chaulya, & Mishra 2010; Mishra, Bolic, Yagoub, & Stewart, 2012; Mishra, Mandal, Kumar, & Sinha, 2013; Mishra, Stewart, Bolic, & Yagoub, 2014; Singh & Mishra, 2016, Mishra, Pratik, & Kumar, 2017; Minhas et al., 2017; Kumar, Chand, & Kumar, 2018). Virtual reality i.e simulation of real-world and imaginary environments and situations with a high degree of realism is a fast growing technology based on information and communication technology. Virtual reality-based training tools can provide simulated exposure to real-world working conditions without the associated risks. However, the training outside the direct working environment provides only limited real-life opportunities. Van Wyk and de Villiers (2009) discussed regarding the virtual reality applications including its appropriate requirements and limitations. Further, Singh & Mishra (2016) presented the need for radar-based systems and virtual reality system in mining industry. A wireless real-time sensing platform using vibrating wire-based sensor has been developed to communicate the geotechnical information wirelessly by means of Zigbee based sensor network to a remote and safer place or even at the surface (Mishra, Pratik, Kumar, Kumar & Mandal, 2018). The developed sensing platform has been integrated with the Internet of Things (IoT) to make the data available to anyone and everyone authorized for the same (Mishra, Kumar, Pratik, Kumar, and Kumar, 2019). They developed a Zigbee based wireless sensor network (WSN) and further extended to IoT with IP enabled gateway. An android based application has been designed for retrieving the data using the corresponding IP address. Further, the display of data on web browser has also been incorporated. Ike, Anthony and Abdulkareem (2013) presented the core application of information and communication technology (ICT) in oil and gas industries for upstream and downstream operations. They presented a case study for the application of ICT in oil and gas sectors. A reliable Internet of Things based architecture for oil and gas industry was presented by Khan, Aalsalem, Khan, Hossain and Atiquzzaman (2017). They proposed a novel IoT based architecture for Oil and gas industries and suggested the methodology for applying the same to upstream, midstream and downstream operations.

Keeping in view of the above, the attempts have been made in the present chapter to discuss the potential applications of IT in the mining industry in the present strategic business scenario. The section 3 of the present chapter deals with the various mining activities and methods as well as key issues to be faced by IT-based systems during implementation. Section 4 discusses the various application sectors of IT in mining industry and section 5 illustrates the application of IT in oil and gas industries followed by future prospects and conclusions in section 6.

3. THE WORLD OF INFORMATION TECHNOLOGY IN MINING

Information is a core component of globalization. However, information is not communication. Communication involves the provision of information in a format and manner that can be used by the beneficiary. Information technology can become an integral part of information dissemination, safety, remote operations, mine mechanization, fleet management, environmental impact due to mining operation,

exploration of coal, minerals, oil and gas, process improvement and efficiency enhancement. It will play even major role in meeting the issues of the sustainable development facing the mining industry in the 21st century with new measures and innovative ideas (Rankin, 2011). However, before going into details of the application of IT in the mining industry, the outline of the mining activities and the key challenges posed during the implementation of IT are equally important to discuss.

3.1 Overview of Mining Activities and Methods

The sequence of activities in modern mining takes place usually in the five stages in the overall life of a mine namely prospecting, exploration, development, exploitation, and reclamation (Hartman & Mutmansky, 2002). The primary stage in the utilization of a mineral deposit is prospecting, the search for ores or other valuable minerals such as coal or nonmetallic. The exploration determines the size and value of a mineral deposit as accurately as possible. The work of opening a mineral deposit for exploitation is performed in the third stage of mining i.e. development. It initiates the actual mining of the deposits. Access to the deposit can be done in two ways either by stripping the overburden (soil and/or rock) to expose the near-surface ore or valuable minerals for mining or by excavating openings from the surface to access deposits buried inside in turn to develop underground mining. Exploitation, the fourth stage of mining, is associated with the actual recovery of minerals from the earth. The method of mining is decided by the characteristics of the mineral deposits keeping in view the restrictions imposed by safety regulators, environmental concerns, the viability of the technology, and economics (Brady & Brown, 2007). Further, the geological conditions, for example, the dip (inclination of a geologic structure from the horizontal), competency of the surrounding rock, and shape and strength of the ore/minerals, also play a key role in selecting the mining method. Conventionally, two mining methods i.e. surface and underground mining methods are taken into consideration. Surface mining is the predominant exploitation procedure worldwide. Open pit or open cast mining method comes under this category. open pit mining method is preferred to exploit a near-surface deposit or one that has a low stripping ratio which can be defined as the ratio of the volume of overburden required to be handled in order to extract some tonnage of ore or other valuable minerals (Okubo & Yamatomi, 2009; Sjöberg, 1996). A thick deposit is normally mined in benches or steps, whereas thin deposits may require only a single bench or face. Underground mining method is usually classified into three categories: unsupported, supported, and caving (Brady & Brown, 2013; Hamrin, Hustrulid, & Bullock, 2001). The unsupported method does not require major artificial support to tolerate superincumbent loads. In this method, the superincumbent loads are managed by the natural competence of the walls of the openings and pillars. However, reasonable amounts of roof bolting and localized support measures such as light structural sets of timber or steel are often employed. This method of mining is used to extract roughly tabular, flat or steeply dipping mineral deposits associated with surrounding rock. Room-and-pillar is the most common unsupported mining method. This method is used for flat-lying seams or bedded deposits like coal, limestone, and salt. In room-and-pillar mining, rooms are excavated and the support of the roof is provided by natural pillars of the minerals that are left standing in a systematic pattern (Wagner, 1980; Hustrulid, 1982; Peng, 2008). Fig. 1 shows the room-and-pillar mining method. Mines, which are having weak rock structures, are usually preferred for supported mining methods. It requires a substantial amount of artificial support to maintain stability during excavation and provide systematic ground control throughout the mine. In general, this method of mining is employed when unsupported and caving methods are not pertinent. Caving method of mining is associated with induced, controlled, massive caving of the overlying rock/ore body or both (Laubscher, 1994). Longwall mining is a caving method (Fig. 2). This method is well

adapted to horizontal seams, usually coal, at some depth. Longwall mining provides complete extraction of the coal contained in a large rectangular block or panel (300m wide and 2 to 3 km long), and subsequently, the roof in the mined-out area is allowed to cave or collapse (Mishra & Kumar, 2017; Peng 2019). Longwall mining consists of self-advancing hydraulic roof supports, a sophisticated coal-shearing machine, and an armored conveyor parallel to the coal face. Operating under the movable roof supports, the shearing machine travels over the conveyor while cutting and spilling the coal onto the conveyor for transportation to the surface. As the shearer cuts the full length of the coal face, it starts moving in the reverse direction without taking turn along the face taking the next cut. The movable support continuously shifts closer to the newly cut face. The steel canopies of the roof support take care of the safety of miners and equipment, while the roof is allowed to collapse. Extraction continues in the same fashion till the entire panel of coal is removed. The final stage, reclamation is the process of closure of the mine in which restoration of land and water takes place. Further, reclamation mitigates and reduces the environmental effects of mining.

Figure 1. Plan view of developed Bord and Pillar mining method for underground coal mines (Not to scale)

3.2 Key Challenges

IT has to face a number of challenges during its implementation in mining industry. To name few (Mishra, Bolic, & Yagoub, 2009; Mishra et al., 2014): i) harsh environment with extremes of temperature, humidity, inflammable gases and dusts, ii) shielding of electromagnetic signals by vehicles, rock, minerals, ore body and metal infrastructure, iii) exposures of explosives, detonators, and high voltages with electromagnetic signals during transmission, iv) lack of adequate infrastructures, v) explosion protection requirement for the electrical and electronic installation in hazardous areas etc.

4. SECTORS OF APPLICATION OF INFORMATION TECHNOLOGY IN MINING

Mining industry is facing many challenges due to its hazardous in nature as well as the globalization of the other industries to compete with them. Demand for coal, minerals and allied product is gradually

Figure 2. Plan View of Longwall Mining for underground coal mine (Not to scale)

increasing due to the industrial and population growth. Therefore, to balance the demand and supply ratio, it is important for mining industry to make the transition from traditional method to technology enabled processes like information technology and automation to improve the safety requirement as well production and productivity. Some of the fundamental roles of Information technology in modern era for economic growth and development are: i) it reduces transaction costs from more expensive means of communicating and transacting the messages from physical travel of personnel/letter/paper from one place to other, ii) it offers immediate connectivity for data, voice and even audio-visual means resulting to improve efficiency, accuracy and transparency, iii) it expands the scope of potential market of the coal, minerals and allied products, iv) it also widen the scope of engaging the suitable skilled personnel as per the requirement of the activity to be performed. Some of the following sectors can be targeted for application of information technology in mining industry:

4.1 Information Dissemination

It goes without saying that information is an important resource in decision making process for any industry. It becomes more vital when the situation is always changing hourly, shift-wise or day-wise such as in mining industry. Since mining is a dynamic process, therefore, the geotechnical and environmental parameters are always varying in case of both underground and open pit mines. Mining activities take place at multiple locations/districts within a mine and a large number of miners and mine personnel are engaged in various activities. Sharing the real time information across the workforce can help in enhancing the output per man shift as well as in fast and suitable decision making. In addition, machine for some particular activity can also be used at other location within the mine resulting to reduce the machine idle time if the previous activity has been completed. Information sharing with miners regarding their rights and obligations under legislation in force can make them aware to their responsibilities (Gibson, 2001). IT can help by displaying their rights and duties periodically at the work place or sending messages/emails etc. to recall. Further, mine management can also engage the suitable skilled personnel overcoming geographic isolation as per the requirement of the activity to be performed. Information technology can help the mine management to create a repository of all the information shared for future best practices by learning from the past experiences. This will also help in eliminating multiple information silos and associated perplexity.

4.2 Safety

The high risk associated with mining operations due to its perilous in nature puts safety on the priority list against the backdrop of various accidents took place in recent years (Mishra, Prasad, & Roy, 2015; Mishra and Kumar, 2017; Kumar, Mishra, & Kumar, 2017; Mishra and Kumar, 2017; DGMS annual report, 2017; DGMS annual report, 2018; MSHA, 2018). Improvement in safety measures can not only help in saving the lives and assets of the industry but also to save costs from insurance claims, accident damages, litigation and production delay. IT will provide internet sites such as local area network (LAN)/wide area network (WAN) for safety measures to be taken during various mining activities. Further, mining industry requires online and real-time geotechnical and environmental monitoring using IT enabled active systems to increase the safety in mining operations to the next level (Song, Rinne, & Van Wageningen, 2013).

Slope stability in open pit mining operation is one of the major concerns for safety which impedes the production of the mine to a large extent. Stability of any slope mainly depends upon the interaction of driving and resisting forces. The driving force causes down slope movement of materials and the resisting force opposes the same and prevents such movements. When the driving force exceeds the resisting force, the downward movements take place, and the slope becomes unstable (Tatiya, 2005). The continuous monitoring of slopes prior to slope failure can be very helpful in protecting life of miners, mining equipment and infrastructure developed for open pit mining operations. Slope failures are in general a result of small scale slope movements sometimes limited to a few centimeters of total displacement. Evaluation of rock slope instability requires the following three parameters (Bieniawski 1989): i) detailed information on the geometry of the exposed rock, ii) analysis of discontinuity properties such as joints, fractures and bedding planes, and iii) definition of the rock mass because these factors determine the mechanical behavior of the rock mass to a large extent. IT enabled 3-D laser scanners can be a suitable mode of accurate and minute monitoring for providing detailed information on exposed rock faces

(Slob, Hack, & Turner, 2002) and provide prior warning before failure. The advent of 3D laser scanners leads to a new method of measuring volumes and examining physical features of the Earth. Turner, Kemeny, Slob, & Hack (2006) evaluated the unstable rock slopes with 3-D laser scanner and developed an algorithm for determining rock discontinuity information and defining block size distribution. Singh (2017) has also highlighted the importance and features of 3-D laser scanner for monitoring the slope stability of open pit mines.

It goes without saying that blasting operation is still prevailing in most of the mines for extraction of coal and minerals, where adequate safety is required as an extensive amount of explosives and detonators are to be dealt with. Identification of the misfired holes is a challenging task if it takes place during blasting. RFID modules installed within or applied upon the explosives materials/articles can be used for real time tracking, tracing and monitoring the explosive materials (Morhard, Gelormino, & Zuckovich, 2007). Further, Mishra et al. (2012) discussed in details the feasibility for locating of misfired holes using RFID including the safety measures to be taken into account.

Strata control problems, which continues to be a major safety concern for underground mines, are very common. The problems include roof fall and side fall, air-blast, pillar crushing, or fall of cantilever behind the longwall face support in case of coal mines. IT can help to prevent such hazards in the following ways: i) continuous monitoring of strata condition and data acquisition, ii) online evaluation of strata behavior and real time and online transmission of the same to management level, iii) online decision making by the mine management, if problem persists with a feasible solution, and iv) giving warning at a very fast rate to the workers of the affected area for evacuation at a safer place. With outstanding advantages and ease of configuration, flexibility to shrink or expand the monitoring range, strong fault-tolerance and mobility, wireless sensor network (WSN) can play an important role in monitoring and analyzing dynamic, hostile and unfamiliar environments.

Toxic and combustible gases, typically found in underground coal mines due to various mining operations, are regarded as a problem of special significance for example, the mixture of various underground gases forms different type of dampers such as black and white dampers which causes suffocation as well reduces intake of oxygen into the blood, respectively affecting the health of miners. Further, hydrogen sulphide (H_2S) is an extremely toxic and irritates the lungs and respiratory tract and can even cause death with high level of exposure (>500 ppm) (Mishra & Kumar, 2017). In addition, the presence of inflammable/combustible gases lead to mine fire if persists beyond threshold limit. Therefore, innovative approaches are needed to improve the health of the miners working in underground. For this purpose, autonomous remote monitoring system or intelligent support system with the provision of audio-visual alarm could be an option. Here, WSN can be an opportunity as it has manifold interfaces to connect multiple environmental sensors for monitored the underground environment easily. Osunmakinde (2013) developed an autonomous remote monitoring framework for monitoring the underground environmental parameters using WSN coupled with intelligent decision making for miners. A number of researchers have developed/proposed the underground environmental monitoring system using WSN. A fuzzy logic approach has been presented using WSN for fire monitoring in underground coal mines by Muduli, Jana, & Mishra (2018). Moridi et al. (2015) proposed an automated underground mine monitoring and communication system based on the integration of WSN and Geographic Information System (GIS). They developed ZigBee nodes for sensing the underground environmental parameters including switching ON and OFF ventilation fans, and texting emergency messages. The system can turn the auxiliary fans remotely or automatically and send evacuation messages to underground miners during unsafe condition. Ray, Majumder, Maity, Roy, & Karmakar (2015) developed a robotic system to remotely

monitor the environment of a hazardous mine tunnel from the surface. The system is equipped with a set of operational sensors such as CO, CO₂, CH₄, temperature and humidity for monitoring underground environment and navigational sensors such as infra red sensors, compass, laser range finder and camera. The robot can be controlled either manually or autonomously and data can be transferred to the over ground monitoring station.

Sudden inrush of water during mining operation is a real threat associated with mining industry especially for those which are operating mines (Mishra & Kumar 2017). In general, additional pumps are engaged to lower the water level and permit miners to escape. If the flooded area is very large then a rescue shaft is developed by drilling. IT can play a significant role by integrating the additional water level sensors including other gas and geotechnical sensors at the strategic places with the WSN.

4.3 Mine Mechanization and Remote Operation

Mining industry is realizing the benefits of mechanization and remote operation in terms of production, productivity, improved efficiency and safety (Bandyopadhyay et al. 2010). In fact, this transforms the mining operations into greater reliance on technology. With the help of modern technology, the equipment involved in various mining operations can be controlled and even management of these operations can also be done remotely. On the other hand, due to minimal human intervention, the chance of manual mistakes will be minimized. Further, if the system will have capability for monitoring the critical parameters of machine health including geotechnical and environmental parameters, the automatic alerts as well as remedial measures will also be provided to initiate corrective actions. However, for effective implementation of mechanization and remote operation for various mining activities, it is vital to ensure that all the systems function in a synchronous manner to enable seamless data exchange. Mining being dynamic in nature and in general located in far flung areas, it offers another challenge namely, connectivity. It goes without saying that laying cables especially in underground mines is difficult and costly affair due to their uneven terrain and cable gets damaged in case of any disaster/hazard and the transmission of information will be stopped. Further, the cable has to be extended periodically as the mining operation progresses. So, the cable will have a number of joints and somehow reduces the performance of transmission. Therefore, wireless remote operation can help in this regard to a large extent (Mishra et al., 2018).

Automated system allows miners and mine personnel to communicate with and control machinery remotely without exposure to dangerous mining environments. It reduces health and safety risks. Automated equipment operates in a controlled fashion and precise manner which reduces machine idle time and in turn improves efficiency. It has been observed in many instances that efficiency improvements translate into reduction in requirements of energy and consumables and offer less wastage of the same (Fisher & Schnittger, 2012).

Further, remote automation relies highly on the use of sensor nodes that are proficient in offering the information needed to manage mining and processing operations. Advances in information processing allow these sensor nodes to evaluate signals and incorporate data from a number of geotechnical and environmental sensors. Artificial intelligence with Global Positioning Systems (GPS) and wireless connectivity with sensor nodes enable driverless trucks to either drive on their own or be driven by a remote operator. Computer systems that supply data on the velocity and position of the vehicle can stop accidents and improve the lifetime of these machines. Productivity loss can be reduced as breakdown regularity diminishes resulting in enhanced productivity and profitability.

4.4 Fleet Management

The productivity of mining operations essentially depends upon the efficient management and effective utilization of fleet. Managing equipment, tracking data, and transporting materials are top priorities especially for open pit mining operators, making fleet management a crucial part of their daily job. Mining industry manages large fleets of vehicles. Therefore, efficient management of these fleets of vehicles is a requirement for the mining industries which can play an important role in the safe transportation of both mine workers and mining materials. In the earlier literatures, many authors indicated that material transportation alone costs 50 to 60% of the total operating expenditure in an open pit mine (Alarie & Gamache, 2002). Reducing these expenditures by even a few percent using information technology will contribute in overall benefit to the mine. The use of information technology can be effective in a number of ways (Chaulya et al., 2008): i) reducing of idle time of machinery, ii) optimizing utilization of heavy earth moving machinery (HEMM), iii) health monitoring of HEMM, iv) quality control, v) crusher throughput management, vi) improving mine safety, vii) extensive online real time reporting of machines, and viii) feeling of mine activity through electronic eye. Whereas, in conventional mining operation/manual dispatch system includes i) manual attendance listing of available equipment, ii) manual allocation of equipment, iii) manual information of equipment, iv) trip counted by trip men, v) manual maintenance schedule and vi) manual report preparation.

Presently, truck dispatch systems are being used in most of the open-pit mines for efficient operation in the following fashion: i) minimizing shovel waiting time by assigning empty truck to the shovel waiting for a truck from long time, ii) minimizing shovel saturation by allocating the trucks to the shovel at equal time intervals to keep a shovel in operation without waiting for trucks, iii) minimizing truck waiting time by allotting an empty truck to the shovel where the truck loading operation will be initiated first, and iv) minimizing truck cycle time. For these purposes, a number of technologies have been integrated with manual dispatching system to minimize the time of operation and make the operation cost effective. Dispatching procedures range from simple relative priority rules (Crosson, Tonking, & Moffat, 1977) to solving linear programming-network flow formulations (Hagenbuch, 1986). Soumis et al. (1986) described a three-part procedure involving consideration of long-term objectives, non linear programming and the classic assignment problem. All of these systems have specific methods of deciding on best truck assignments. Lizotte, Bonates, Leclerc (1987) and Batchelor (1987) have reviewed and described the benefits of previous dispatching systems. They also designed and implemented the dispatching system using computer simulations. A tracking and monitoring system for opencast mines has been investigated by Bandyopadhyay, Chaulya, & Mishra (2014). The system has the capability of continuously tracking and monitoring the HEMMs and moveable equipment in opencast mines using ZigBee-enabled active RFID devices forming a dynamic wireless network among them and other static and mobile ZigBee devices placed at strategic locations. Use of system would help in i) maintaining computerized record and analyzing the performance of costly shovels and dumpers deployed in opencast mines, ii) optimizing the placement of dumpers with each shovel depending on the change in working and dumping places, iii) maintaining computerize attendance of dumper operators and other personnel working in an opencast mine, iv) providing warning to the signal man and dumper operator, while dumper approaching close proximity to the signal man, v) establishing two-way message communication among the personnel engaged in an open-pit mine and vi) improving production, productivity and safety in open-pit mine.

Keeping in view the developing pace of technology, the days are not far when that fleet management system of mining industry would explore smart information system by fusing IT with operation technology (OT). A proof of concept for cloud technology based fleet management system has also been suggested by Sodeyama, Takada, Hane, Furuno, & Watanabe, (2015). The said system consists of the following sub-modules: i) a server that runs the fleet management system software, ii) units installed in each vehicle to connect to the server via a wireless local-area network, and iii) the client applications that the dispatchers use for their work. The dispatchers use their client applications to monitor vehicle status and issue commands to the vehicle operators. The server stores production data collected during extraction process, production totals and details of vehicle operation. The server is commonly put in a room at the mine location, where its operation is administered by on-site system technicians. There are following five advantages of the system as claimed by the authors: i) remote dispatching, ii) ease of installation, iii) reliability and stability, iv) on-demand use, and v) access from mobile devices.

4.5 Exploration of Coal and Minerals

It goes without saying that exploration of coal and mineral is the first phase of mining cycle. However, most explorations do not turned into mine. Geographic information system (GIS) helps in managing data related to geographic locations in terms of compilation, processing, analyzing, displaying, and storing extensive amount of data. GIS It plays a crucial role in exploration of coal and minerals (Bonham-Carter, 1994). GIS replaced traditional map-analysis processes, drawing tools, and drafting and database technologies. GIS has helped in a number of mining operations from exploration to stope development, and production to mine rehabilitation. In case of exploration, GIS is an ideal tool for integrating various datasets such as geophysical images, geologic maps, radiometric surveys, geochemistry, boreholes, and mineral deposits. The main approaches in generating mineral potential maps using GIS are (Porwal & Carranza, 2015): i) establishing the exploration conceptual model, ii) building a spatial database, iii) analyzing the spatial data such as extraction of evidence maps, and iv) combination of evidence maps to predict mineral potential. It is obvious from the above discussion that mining organizations can use GIS to target mineral exploration, evaluate mining conditions, model mine construction and display geochemical or hydrological data. Therefore, information technology and computer methods have become the integral part of mineral exploration and mineral processing and management.

4.6 Environmental Impact of Mining Operations

Mining operations basically impact on the following environmental parameters: i) water resources, ii) air quality, iii) soil quality, and iv) carbon budget.

From water monitoring to air quality, information technology can save users operational time and resources by getting data to mining personnel without requiring them to spend hours in the field. Automatic information gathering and analysis help mine management to save on operating and maintenance costs and extend asset life, while at the same time complying with stringent regulatory and safety requirements. Innovative wireless systems allow field data to be captured and automatically downloaded when the unit is installed, eliminating human error during data transfer (Osunmakinde, 2013).

4.7 Process Improvement

Mining organizations need to ensure process improvement to remain cost effective and competitive from mining to material extraction and marketing to sales and transportation. Information technology can help to analyze and optimize organizational processes for improving efficiency. IT can help to make available the up-to-date operational information to the mine management to improve the mining operation and machine health, if required. Accurate and relevant information can be made available regarding production and sale online with only authorized access which in turn helps in marketing.

5. INFORMATION TECHNOLOGY IN OIL AND GAS INDUSTRIES

IT can help in upstream and downstream operations of oil and gas sectors. Upstream operations include exploration and production of crude oil and facing the challenge of increasing oil production and improving the rate of oil recovery. IT can assist in collecting huge amounts of data concerning to oil fields. Those data can be extrapolated by means of computational models for decision making with respect to optimal oil recovery methods. Horizontal drilling of oil wells requires accuracy in data management. By using well logging devices during drilling, the data from the oil wells can be transmitted to the management to ensure best practices. Downstream oil operations involve transportation and refining of crude-oil and processing and purifying the raw natural gases including marketing and distribution. IT can optimize the overall supply chain of oil and gas sectors.

6. FUTURE RESEARCH DIRECTIONS

Seeing the pace of development in information technology, it goes without saying that the future scenario of mining and allied industries will be a digital landscape. Technologies such as robots, robotic trucks, 3D printing, and automated exploration drones, autonomous stockpile management, autonomous robots for recovery of recycling material, pit drones, smart sensors, and industrial internet of things (IIoT) offer opportunities for mining and metal companies to revolutionize their operations and create remarkable value. It is worth mentioning that involving information and communication technologies with coal and mineral excavation including oil and gas exploration will lead towards an intelligent and unmanned operation in the near future.

7. CONCLUSIONS

Information and communications technology can be employed to the entire value chain and lifecycle of mining and mineral extraction. Further, upstream and downstream operations of oil and gas industries can also reap the benefits of the application of information and communication technology apart from the marketing and transportation. Exploitation of information technology for storing data, analysis and prediction of results helps in better control and optimization of mining operations. Data storage helps to quickly respond to information and remain successful in competitive market. By use of information technology, complaints can be reduced which in turn improve efficiency. Application of information technology can help in a number of key areas as said in the preceding sections, for example informa-

tion dissemination, safety, remote operations, mine mechanization, fleet management, environmental impact, exploration of coal and minerals, process improvement and efficiency. In addition, intelligent mining has the potential to avoid mistakes that result in loss of lives and expensive write-off of assets.

ACKNOWLEDGMENT

The author is thankful to the Director, CSIR-Central Institute of Mining and Fuel Research, Dhanbad, India for his encouragement and support as well as permitting the author for publishing the Chapter. The views expressed in this paper are that of the author and not necessarily of the organization they belong to.

KEY TERMS AND DEFINITIONS

Coal: Coal is basically a fossil fuel. It is the altered form of prehistoric vegetation that originally accumulated in swamps and peat bogs. High temperatures and pressures caused physical and chemical changes in the vegetation, transforming it into coal.

Information Technology: Information technology is the science and activity of moving data digitally.

Mine: An excavation made in the earth to extract coal and minerals.

Minerals: A naturally occurring inorganic element or compound with an orderly internal structure and a characteristic chemical composition, crystal form and physical properties and has been formed as a result of geological processes.

Mining: The activity, occupation, and industry pertaining to extraction of coal and minerals.

An Approach for Estimating the Opportunity Cost Using Temporal Association Rule Mining and Clustering

Reshu Agarwal

Department of Computer Science, G. L. Bajaj Institute of Technology and Management, Greater Noida, India

INTRODUCTION

Inventory control is a process employed to maximize a company's use of inventory. The main objective of inventory control is to keep the total cost associated with the system to a minimum. This requires familiarity with supply sources, price negotiations including bulk quantity discounts, modes of transportation, budgeting, physical handling, record keeping, and monitoring the incoming quality of items. In real life situations, there are very large numbers of items in an inventory. It may not be possible to review (which includes computing inventory-on-hand, placing orders, receiving stock etc.) such a large number of items with equal intensity. Review activities take time and cost money. Hence items are usually classified into important and less important groups. The important ones get more attention than the others. The goal is to keep stocks at low level while giving good service.

Traditionally, ABC analysis has been based on the criterion of dollar volume and on the principle that there are a relatively small number of items. However, over the last 30 years, there has been an accumulation of research questioning this focus on a single criterion—the dollar volume. Several researchers suggested that multiple criteria should be used in the classification of inventories (Flores & Whybark 1987; Lenard & Roy 1995). However, the problem is that the profit of one item not only comes from its own sales, but also from its influence on the sales of other items or reverse, i.e., the cross-selling effect (Anand et al., 1997). In such a situation, it should be explained clearly whether the cross-selling effects would influence the ranking of items or not, and how to group the items if such effects existed, not concerning what and how many criteria could be used. For effective inventory management, lost sales should also be considered. Lost sales means the customer is impatient and may buy the products from other suppliers because of the shortage, the unmet demand is lost and opportunity cost (OC) of lost sales therefore occurs. Most researchers agree on selecting a constant value as the unit opportunity cost (UOC) of lost sales. Sharma & Sadiwala (1997) considered UOC as a constant value. However, such constant value should not be arbitrarily assigned. Sung & Seok Ock (1992) and Hsu & Lowe (2001) proposed that the penalty cost of lost sales can be estimated by customer goodwill loss. However, they do not provide a quantitative method to estimate the value of the goodwill loss. Many researchers (Wang (2002); Pentico & Drake (2009)) have considered opportunity cost by considering goodwill loss. Though, there are many models for calculating opportunity cost by considering goodwill loss, but there are very few models that have proposed a specific method to estimate the opportunity cost and the goodwill loss.

Further, Brijis *et al.* (2000) proposed a PROFSET model to select only the most valuable items for customized marketing. It determines the most profitable categories based on their profit lift into frequent item-sets of interest, by solving an all-binary optimization problem. The resulting categories imply a high

DOI: 10.4018/978-1-7998-3473-1.ch046

monetary value and the ability to initiate cross-selling in the respective customer segment. However, the PROFSET model does not consider the strength of relationship between items. Also, it does not provide relative ranking of selected items, which is important in classification of inventories. Therefore, the PROFSET model cannot be used to classify inventory items. Kaku & Xiao (2008), further extended inventory classification considering cross-selling effect and ABC classification. The main drawback of this model is that they have not considered that whether and how the quality of association with related items impacts such ranking methodology. Xiao et al. (2011) classified inventory items which are correlated each other using the concept of cross-selling effect together with ABC classification and loss profit. The main advantage of this model was that they ranked inventory items in such a way that it helps inventory manager in really perceiving most profitable items. They classified items based on loss rule (Wong et al. 2005). The loss profit of item/item set is characterized as the basis for assessing the significance of item, in view of which inventory items are classified. They disclosed that to pass judgment on the significance of a item (set), it is not only by looking at the profit it brings in when it is on the shelf, yet additionally the loss profit it might remove when it is missing or stock out. Further, Many reaeachers (Mittal et al. (2015a, 2015b); Agarwal et al. (2016); Agarwal(2017a, 2017b)) have determined ordering policy using data mining algorithms. The opportunity cost of lost sales should be equal to the sum of lost sales of the unmet demand and the ADU brought by the associated products (Kaku *et al.*, 2011). However, they have not calculated opportunity cost for various clusters and particular time-periods.

Proposed Approach

In this chapter, how to estimate the opportunity cost, which are correlated each other is discussed by using the concept of ‘cross-selling effect’. We have discussed two cases for calculating the opportunity cost with cross-selling effect.

Case 1: A mathematical model to estimate the opportunity cost based on association rules considering cross-selling effect in different clusters.

An association rule is an implication expression of the form $X \rightarrow Y$, where X and Y are disjoint item-sets, i.e $X \cap Y = \emptyset$. The strength of an association rule can be measured in terms of its support and confidence. Support determines how often a rule is applicable to a given data set, while confidence determines how frequently items in Y appear in transactions that contain X .

Let $I = \{i_1, i_2, i_3, i_4, \dots, i_m\}$ be a set of items. Now, support of item i_1 is defined as the frequency of its occurrences in total transactions and confidence is defined as conditional probability of purchasing i_2 when i_1 is purchased and is given by formula:

$$Support(i_1) = \frac{Frequencyof i_1}{TotalnumberofTransactions} \quad (1)$$

$$Confidence(i_1 \rightarrow i_2) = \frac{Supportof i_1 \cup i_2}{Supportof i_1} \quad (2)$$

The clustering algorithm aims to minimize the cost due to large items and small items (Wang *et al.*, 1999). The overview of the clustering algorithm is described in Figure 1.

Figure 1. Overview of clustering algorithm

```

/* Allocation phase */

(1) while not end of the file do
(2) read the next transaction <t,- >;
(3) allocate t to an existing or a new cluster Ci ;
(4) write <t, Ci >;
/* Refinement phase */

(5) repeat
(6) not_moved = true;
(7) while not end of the file do
(8) read the next transaction <t, Ci >;
(9) move t to an existing cluster Cj to minimize Cost C;
(10) if Ci ≠ Cj then
(11) write <t, Cj >;
(12) not_moved=false;
(13) eliminate any empty cluster;
(14) until not moved;

```

Further, if the sale of item I_i is lost, all the purchasing patterns that contain I_i will not happen with the corresponding probability, until I_i is replenished. Hence, with regard to item I_i , it is reasonable that the total opportunity cost (TOC) in all transactions should be the DU of all possible item groups associated with item I_i (Kaku *et al.*, 2011).

Let $\text{sup}(\{I_i\})$ be the support of one-item set $\{I_i\}$, $\text{sup}(\{I_i, I_j\})$ be the support of two item set $(\{I_i, I_j\})$ and r_i is the unit DU of item I_i . The TOC of item I can be given by equation:

$$C_i = r_i \cdot \text{sup}(\{I_i\}) \cdot \{T\} + \sum_{I_j \in I - I_i} r_j \cdot \text{sup}(I_i, I_j) \cdot \{T\} \quad (3)$$

Let $\text{conf}(\{I_i \otimes I_j\})$ be the support of the association rule of $I_i \otimes I_j$. From equation (1), we can easily get the UOC of item i , which is represented by UOC_i as equation (2). As well as, the ROC, i.e., Ratio of TOC to DU (ROC in short) of item I is denoted as ROC_i , which is formulated in equation (3).

$$\text{UOC}_i = r_i + \sum_{I_j \in I - I_i} r_j \cdot \text{conf}(\{I_i \rightarrow I_j\}) \quad (4)$$

$$\text{ROC}_i = 1 + \sum_{I_j \in I - I_i} \frac{r_j}{r_i} \cdot \text{conf}(I_i \rightarrow I_j) \quad (5)$$

Thus, the opportunity cost (OC) is defined from the point view of association rules in each cluster.

Case 2: A mathematical model to estimate the opportunity cost based on association rules considering cross-selling effect in various time-spans.

Association rules are used to determine strength between relationships. The general temporal association rule is of the form $(P \Rightarrow Q)^{MCEP(PQ)}$ where $MCEP(PQ)$ is the maximum common exhibition period of items. Let $I = \{i_1, i_2, i_3, \dots, i_m\}$ be a set of m distinct items. The item-set could represent different items in a supermarket. A transaction T is a set of items I . A transaction could represent customer purchases of some items from a supermarket. A database Db is a set of transactions. Furthermore, the rule $(P \Rightarrow Q)^{MCEP(PQ)}$ is frequent if and only if $support((P \Rightarrow Q)^{MCEP(PQ)}) \geq min_supp$ and $confidence((X \Rightarrow Y)^{MCEP(PQ)}) \geq min_conf$ (Lee *et al.*, 2003). The working of temporal association rule mining algorithm is shown below:

Step 1: Firstly, the database is partitioned according to the exhibition period. An association rule $(A \Rightarrow B)^{MCEP(AB)}$ is called a general temporal association rule where $MCEP(AB)$ is the maximum common exhibition period of items.

Step 2: After 1st scan of database, candidate 2-temporal-item-set can be found.

Step 3: Candidate 2-temporal-item-set can be used to produce candidate temporal item-set and sub item-sets.

Step 4: After 2nd scan of database, find all frequent temporal item-set and sub item-sets.

Step 5: Generate all rules that satisfies minimum confidence values i.e. the rule $(A \Rightarrow B)^{MCEP(AB)}$ is frequent if and only if $support(A \Rightarrow B)^{MCEP(AB)} \geq minimum\ support\ and\ confidence$ $(A \Rightarrow B)^{MCEP(AB)} \geq minimum\ confidence$.

Further, if the sale of item I_i is lost, all the purchasing patterns that contain I_i will not happen with the corresponding probability, until I_i is replenished. Hence, with regard to item I_i , it is reasonable that the total opportunity cost (TOC) in all transactions should be the DU of all possible item groups associated with item I_i (equation 3,4 and 5).

Thus, the opportunity cost (OC) is defined from the point view of association rules in each time-period.

Numerical Example

Case 1: An example is shown to illustrate the approach of calculating opportunity cost of frequent items in each cluster. Let the set of items be $I = \{A, B, C, D, E, F, G, I\}$ and the corresponding unit DU is $r_A = 30.00, r_B = 20.50, r_C = 45.52, r_D = 50.00, r_E = 45.52, r_F = 40.00, r_G = 32.00, r_I = 23.00$

The parameters required are given below:

Table 1. An inventory transaction database

TID ITEMS
TID1 a b c
TID2 a b c d
TID3 a b c e
TID4 a b f
TID5 d g h
TID6 d g i

Minimum support, $\min_sup = 60\%$

Minimum confidence, $\min_conf = 75\%$

Each row in Table 1 can be taken as an inventory transaction. The association rule can be identified from these inventory transactions using the apriori algorithm..

Consider the transaction database of Table 1. It is assumed that the user-specified minimum support is 60%. A large item must be contained in at least 4 transactions (i.e., $6 * 60\%$). By applying clustering algorithm, the transaction database of Table 1 is clustered into two clusters consisting of $C_1 = \{tid1,$

Table 2. Opportunity cost of items in Cluster C1

Table 3. Opportunity cost of the items in the numerical example

Clusters	Frequent Items	TOC	UOC	ROC
Cluster C1	A	474.08	118.52	3.9505
	B	474.08	118.51	5.7806
	C	429.1	127.85	2.8087
Cluster C2	D	223	146.5	2.23
	G	223	111.5	3.278

tid2, tid3, tid4} and $C_2 = \{\text{tid5, tid6}\}$. After applying apriori algorithm on both clusters, we find item-set {a, b, c} is the most frequent item-set in cluster C_1 and item-set {d, g} is the most frequent item-set in cluster C_2 .

After calculating the support and the confidences of all frequent items in each cluster, the OC of lost sales in cluster C1 can be calculated as in Table 2 by using equations (3)-(5). Similarly, the opportunity cost of lost sales in cluster C2 can be calculated as shown in Table 3.

Observations

1. Consider cluster C1, the unit DU of item 'B' is the smallest in all items. However, the ROC of its lost sales is the largest. That implies, the item whose OC is the biggest may not be the most costly one which holds the biggest DU. Due to cross-selling effect, the OC of lost sales relies upon the way that what number of related items the item has. Consequently, the inventory model ought to recognize the interdependencies between items.
2. Consider cluster C1, item 'A' and item 'B' has same number of occurrences in the database. The item 'B' has a very small unit of dollar usage and occurrences of only four times in cluster, yet it holds the biggest ROC, because there are many items associated with item 'T'.
3. Consider cluster C2. Obviously, the unit DU of item 'G' is the smallest in all items. However, the ROC of its lost sales is the largest due to the fact that many items are associated with item 'G'.

Therefore, in inventory management, we should consider not only the profit of an item itself, but also the profit of its associated item.

Case 2: An example is shown to illustrate the approach of calculating opportunity cost of frequent items in each time-period. Let the set of items be $I = \{P, Q, R, S, T, U\}$ and the corresponding unit DU is $r_P = 5.00, r_Q = 4.00, r_R = 3.00, r_S = 2.00, r_T = 2.00$, and $r_U = 1.00$. Consider minimum support, $\text{min_sup} = 30\%$ and minimum confidence, $\text{min_conf} = 50\%$.

Consider the inventory item-set be $I = \{P, Q, R, S, T, U\}$ and inventory transaction set (TID) be: $\text{TID} = \{\text{TID1, TID2, TID3, TID4, TID5, TID6, TID7, TID8, TID9, TID10, TID11, TID12}\}$ shown in Table 4. Each row in Table 4 can be taken as an inventory transaction. S1, S2 and S3 are three partitions of the database db, in accordance with the month. As a result, a partial database $\text{db}^{2,3} \subseteq \text{Db}$ consists of partitions S2 and S3. Similarly, $\text{db}^{1,3} \subseteq \text{Db}$ consists of partition S1, S2 and S3 and $\text{db}^{3,3} \subseteq \text{Db}$ consists of partition S3. Using support-confidence framework, the temporal association rules can be identified from the database.

Table 4. An inventory transaction data base

TID	TID1	TID2	TID3	TID4	TID5	TID6	TID7	TID8	TID9	TID10	TID11	TID12
Items	Q,S	Q,R,S	Q,R	P,S	Q,R,T	S,T	P,Q,R	Q,R,S,T	R,T,U	Q,T,U	P,S	Q,S,U

Table 5. Scanning database for first time

S1 C2 Start Count QS 1 2 QR 1 2 RS 1 1 PS 1 1	S1+S2 C2 Start Count QS 1 3 QR 1 5 QT 2 2 RT 2 2 ST 2 2 PQ 2 1 PR 2 1 RS 2 1	S1+S2+S3 C2 Start Count QS 1 4 QR 1 5 RT 2 3 ST 2 2 QT 2 3 QU 3 2 RU 3 1 TU 3 2 PS 3 1 QS 3 1 SU 3 1
---	--	---

Further, 1st scan of database is done. The database $db^{1,3}$ is considered which has three sub-partitions S1, S2 and S3. After scanning the first partition S1, we got four transactions {QS, QR, RS, PS}. Table 5, shows the scanning of database S1, S1+S2, S1+S2+S3.

After 1st scan database db, the candidate item-sets are as follows:

Candidate temporal item-set: $\{QR^{1,3}\}$, $\{QS^{1,3}\}$, $\{RT^{2,3}\}$, $\{QT^{2,3}\}$, $\{QU^{3,3}\}$, $\{TU^{3,3}\}$.

Table 6. Scanning database for second time

Candidate		Count	S ^r
C1	$\{Q^{1,3}\}$	8	4
	$\{S^{1,3}\}$	7	4
	$\{R^{1,3}\}$	6	4
	$\{Q^{2,3}\}$	5	3
	$\{T^{2,3}\}$	5	3
	$\{R^{2,3}\}$	4	3
	$\{Q^{3,3}\}$	2	2
	$\{T^{3,3}\}$	2	2
	$\{U^{3,3}\}$	3	2
C2	$\{QR^{1,3}\}$	5	4
	$\{QS^{1,3}\}$	4	4
	$\{QT^{2,3}\}$	3	3
	$\{RT^{2,3}\}$	3	3
	$\{QU^{3,3}\}$	2	2
	$\{TU^{3,3}\}$	2	2

Table 7. Pruning stage

Candidate Count
C1 {Q ^{1,3} } 8
{S ^{1,3} } 7
{R ^{1,3} } 6
{Q ^{2,3} } 5
{T ^{2,3} } 5
{R ^{2,3} } 4
{Q ^{3,3} } 2
{T ^{3,3} } 2
{U ^{3,3} } 3
C2 {QR ^{1,3} } 5
{QS ^{1,3} } 4
{QT ^{2,3} } 3
{RT ^{2,3} } 3
{QU ^{3,3} } 2
{TU ^{3,3} } 2

Further, Table 6 depicts the 2nd scan of the database and Table 7 shows the pruning stage in which if candidate item-set does not satisfy minimum support requirement is pruned.

After 2nd scan of database db, the frequent item-sets are as follows:

{Q^{1,3}}, {S^{1,3}}, {R^{1,3}}, {Q^{2,3}}, {T^{2,3}}, {R^{2,3}}, {Q^{3,3}}, {T^{3,3}}, {U^{3,3}}, {QR^{1,3}}, {QS^{1,3}}, {QT^{2,3}}, {RT^{2,3}}, {QU^{3,3}}, {TU^{3,3}}.

The final temporal association rules after 2nd scan of database are shown in Table 8.

Table 8. Temporal association rules after 2nd scan

Rules	Support	Confidence
(Q=>S) ^{1,3}	33.33%	50.00%
(S=>Q) ^{1,3}	33.33%	57.00%
(Q=>R) ^{1,3}	41.67%	62.50%
(R=>Q) ^{1,3}	41.67%	83.33%
(Q=>T) ^{2,3}	37.50%	60.00%
(T=>Q) ^{2,3}	37.50%	60.00%
(R=>T) ^{2,3}	37.50%	75.00%
(T=>R) ^{2,3}	37.50%	60.00%
(Q=>U) ^{3,3}	50.00%	100.00%
(U=>Q) ^{3,3}	50.00%	66.66%
(T=>U) ^{3,3}	50.00%	100.00%

Hence, items Q, S, R are frequent in time-period from January to March, items Q, T, R are frequent in time-period from February to March and items Q, U, T are frequent in time-period of March only. After calculating the support and the confidences of all frequent items in each time-period, the OC of lost sales in time-period of January to March can be calculated as in Table 9 by using equations (3)-(5).

Similarly, the opportunity cost of lost sales in time-period from February to March and March only can be calculated as shown in Table 10.

Table 9. Opportunity cost of items in time-period from January to March

Observations

1. Consider the time-period from January to March, the unit DU of item 'S' is the smallest in all items. However, the ROC of its lost sales is the largest. Because of cross-selling, the OC of lost sales depends on the fact that how many associated items the item has.
2. Consider the time-period from February to March, item 'Q' and item 'T' has same number of occurrences in the database. The item 'T' has a very small unit of dollar usage and occurrences of only five times given time-period, yet it holds the biggest ROC, because there are many items associated with item 'T'.

Table 10. Opportunity cost of the items in the numerical example

Time-Span	Frequent Items	TOC	UOC	ROC
January to March	Q	65	8.125	2.031
	S	50	6.571	3.286
	R	54	8.999	2.999
February to March	Q	45	9	2.25
	T	37	7.25	3.625
	R	38	10	3.334
March only	Q	13	6.5	1.625
	U	13	6.5	6.5
	T	13	6.5	3.25

3. Consider the time-period of March only. Obviously, the unit DU of item ‘U’ is the smallest in all items. However, the ROC of its lost sales is the largest due to the fact that many items are associated with item ‘U’.

Therefore, in inventory management, we should consider not only the profit of an item itself, but also the profit of its associated items.

With the help of results obtained, retail stores like wal-mart, reliance fresh and big bazaar, can analyze their inventory data in a more realistic way. Their data can be mined using temporal association rule mining to predict patterns in particular time-periods. These patterns can be further used to estimate opportunity cost of lost sales of frequent items in particular time-periods, which will help the retail stores to predict loss profit more accurately. This approach results in higher profit to the stores.

CONCLUSION

Introducing correlations of inventory items into inventory policies is very natural because such situations often occur in the real world. In this chapter, we have discussed to calculate opportunity costs which are correlated each other by using the concept of ‘cross-selling effect’. We have discussed two cases for estimating opportunity cost with cross-selling effect. In Case 1, temporal association rule mining has been applied to find relation between item-sets. This relationship is used to determine the customer’s purchasing behaviors considering cross-selling effect and various time-spans. However, this case does not classify inventory items considering similarity between transactions. In case 2, association rule mining has been applied to find relation between item-sets. This relationship is used to determine the customer’s purchasing behaviors considering cross-selling effect and various clusters. The lost sales of one item can influence the other item’s sales, which can be characterized by association rules. Based on this idea, we have considered different clusters to estimate the OC of frequent items. The opportunity cost is the sum of the profit of the item itself and the ADU that made by the related items. Results suggest that, the cheaper items may have larger OC in consideration of cross-selling effect, which depends on how many associated items they affect.

Future Research Directions

A future study would be extended to propose the model by using combination of various data mining techniques in order to integrate the associated demand and the lost sales into the multi-item inventory model. Also, an inventory model will be proposed considering time series in scenario, where variables are correlated.

KEY TERMS AND DEFINITIONS

Association Rule Mining: It is used for searching interesting relationships among items in a given data set.

Clustering: It is defined as a group of similar elements.

Cross-Selling Effect: It describes the dependency of purchase of one item onto the purchase of another item.

Opportunity Cost: It is the profit lost when one alternative is selected over another.

Temporal Association Rule Mining: It discovers valuable relationship among the items in particular time periods.

Systems, Services, Solutions of the Public Cloud

INTRODUCTION

Cloud computing impacts the way people interact with technology, at least for consumers. Users no longer store personal data on a single device, but instead access it from a range of devices. When people purchase a new phone, they need only to link it to the appropriate provider to access their contacts, calendar and other data, whether it be documents, photographs or financial statements, and they can exchange one device for another seamlessly and still be able to do what they wish to do. If an individual device fails, it may be inconvenient, but ultimately it does not involve loss of data or prevent access to the data from another device. As providers hold an up to date copy of the data, a user may for instance begin working on a presentation on a PC, continue working on it on a tablet, and decide to do some light editing on a smart phone.

What is not quite as clear is how these underlying technologies both function and coalesce, and moreover how organizations are to leverage the cloud to bring value to a range of stakeholders and interested parties. This article begins by outlining the fundamentals of cloud computing, concepts like service models and how cloud computing may or may not interact with traditional on-premise infrastructure. Then it considers the at times vexed, contentious questions of risk, security, governance and compliance. Once these questions are addressed and the suitable technologies properly implemented, the cloud is capable of delivering to organizations accelerated innovation and quality. This potential is reflected in the growth of the public cloud. European, Middle Eastern and Asian (EMEA) organizations sourced 35% of their total IT infrastructure from the cloud in 2017 and by 2022 this is forecast to grow to 63% (Scott, 2018).

BACKGROUND

A common view of the cloud is that it is nothing new, that people have been using centralized computing in the form of mainframes for instance. While this sheds light on some of the similarities between mainframes and the cloud, it does not reflect the differences between them, differences that are significant. One useful analogy is to compare the cloud and earlier technologies, with the smart phone and the traditional telephone. While the telephone as such is not new and the smart phone can do the same kinds of things as the traditional phone, it is much more flexible and powerful, and this is down to, in large part, how mobile devices take advantage of the cloud, making them more functional and helping extend battery life (Liu, Chen, Ma, & Xie, 2016). As a term “cloud computing” is problematic because it does not mean one thing, but is “an umbrella term” (Missbach, Stelzel, Gardiner, Anderson & Tempes 2013) that refers not just to a set of technologies but a new model of delivering a wide range of computing resources, services and solutions.

DOI: 10.4018/978-1-7998-3473-1.ch047

Fortunately, the National Institute of Standards and Technology (NIST) has made a deliberate effort to define cloud computing and done this well, so much so that its three-page description of this term is now considered the standard for the industry. NIST defines cloud computing as “a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction” (Mell & Grance, 2011). This definition is comparable to the four key characteristics of cloud computing as “pay-per-use”, “elastic capacity and the illusion of infinite resources”, a “self-service interface” and “resources that are abstracted or virtualised” (Voorsluys, Broberg, & Buyya, 2011). The cloud is “ubiquitous”, “convenient”, and “on-demand” in the sense that users can access applications and data from anywhere and at any time, and because organizations (or “customers” as the literature often calls them) can, without having to talk to anyone, provision computing resources and services from a “shared pool of configurable computing resources,” a business model that involves renting multi-tenanted infrastructure.

SERVICE MODELS

Cloud providers, through the use of virtualization, essentially abstract the software, whether it be a server, a database or a network from the underlying physical infrastructure and offer customers logical software-defined computing resources and services that they can customize, secure, provision and manage in a way that meets their needs and requirements (Buyya, Vecchiola, & Thamarai Selvi, 2013). The service models in cloud computing all reflect this principle of abstraction and represent different sets of responsibility depending how much or how little customers wish to outsource. Infrastructure as a Service (IaaS), Platform as a Service (PaaS) and Software as a Service (SaaS) therefore represent progressively lower levels of engagement on the part of customers, as they cede more of their responsibilities to the cloud provider.

With IaaS, customers no longer need to purchase physical equipment and associated infrastructure, and manage it, whether it is a server in the case of a small business or a large datacenter in the case of a large business. They can instead utilize the provider’s resources presented to them in the form of *virtual* infrastructure such as virtual machines (VMs), networks, storage, firewalls, and load balancers, all on a granular pay-as-you-go basis, so that the customer pays for example for each hour of use of a small VM, which will be cheaper than a more powerful VM. While the benefits outweigh the constraints, customers need to know not just what the provider can but also what it cannot do and work within the limitations of a particular cloud. For instance, in Microsoft Azure once a virtual network has been created it is not possible to add a virtual machine to it. There are workarounds, for instance keeping the disk with the data and connecting them to newly created VMs in the existing virtual network.

In the case of PaaS, customers have no access to or control over not just to the underlying physical but also virtual infrastructure, such as servers, networks, storage and operating systems. PaaS involves the provision of resources and services, such as a development environment, database, and integration and development tools that can be used in a matter of minutes, all provided so as to reduce the effort and cost for SaaS vendors (Brown & Nyarko, 2013). Customers can instead focus on the functionality and logic of applications. It is the responsibility of the provider to ensure that a database for instance can cope with the increasing demands made on it and that the underlying operating system is properly patched and secure. Well-known examples of PaaS are AWS Elastic Beanstalk and Force.com (part of Salesforce.com). In terms of IaaS and PaaS, Amazon Web Services (AWS) is currently the largest public

cloud provider and Microsoft the second largest public cloud provider, with 57% and 20% of enterprises making use of them respectively (RightScale, 2016). This is in line with the Gartner magic quadrant (Leong, Toombs, & Gill, 2015).

SaaS is a fully-built software solution that customers can use immediately. It is an application that is owned by the provider, who takes responsibility for all aspects of its development, deployment and operation (Carstensen, Morgenthal, Golden, 2012) as well as for security, performance and availability. The application is accessed through a network connection by the customer, who usually pays a subscription of some kind instead of the traditional upfront license fee, which costs a great deal more because it gives the customer a permanent right to use the software whereas the subscription does not. The application or set of applications is hosted on a remote system and the customer data is stored by the provider but the customer can access the application or set of applications and the data from various devices and systems. Well-known examples of SaaS are Microsoft Office 365 and Salesforce.

DEPLOYMENT MODELS

NIST identifies four cloud deployment models: private cloud, public cloud, hybrid cloud and community cloud (Mell & Grance, 2011). The private cloud is owned and operated by a single organization that may have various customers, such as departments or business units. The organization is completely responsible for managing all aspects of the private cloud: procurement, configuration, maintenance, support and delivery of services. As a result, there are usually few significant cost savings or economies of scale or pooling of resources typical of the public cloud. Some commentators argue that few organizations will implement an on-premise cloud environment that satisfies the NIST definition because that is not only expensive but is also technically a highly complex undertaking (Golden, 2015). When most people refer to the “cloud,” they are thinking of the public cloud, a cloud entirely owned and managed by an external third-party provider. In most cases the public cloud involves shared third-party infrastructure, though exceptions can be made for those customers willing to pay a premium for hardware dedicated for their exclusive use.

The hybrid cloud acknowledges that most organizations would wish to continue making use of on-premise infrastructure that current IT staff know and understand while being able to take advantage of the public cloud and associated services. While the hybrid cloud is meant to be a private cloud that expands into the public cloud, in reality it may not entail the use of a private cloud at all and may instead simply be a more traditional on-premise virtual infrastructure that connects securely with one or more public clouds to form a single hybrid entity. One example of this is the use of compute in the public cloud while retaining data on local on-premise systems. Another is the use of SaaS that integrates seamlessly with existing environments. This is now being extended to the connection of not one, but multiple clouds as various companies take the view that most organizations are likely to make use of a number of providers and that these clouds need to be connected seamlessly (Schwartz, 2015).

The community cloud is typically a private cloud in which a number of entities share the cost and benefits, while avoiding some of the concerns around security and regulation associated with the cloud. This works best when the entities share similar security, governance and policy requirements (Bond, 2015). For example, multiple government agencies may make use of a single datacenter, with the result that less of their interactions traverse the internet (Winkler, 2011). While this satisfies regulatory and compliance requirements, it is not likely elastic or even highly available, and is typically only IaaS, with managed services having to still be built and maintained. The community cloud, though, may also be

part of an external, public cloud that has been especially designed and provisioned for that purpose. The Microsoft Office 365 Government Community cloud is an example of this. It satisfies a particular set of requirements: data is stored in the United States, customer data is restricted to screened Microsoft personnel and satisfies all the requirements of US public sector customers (Microsoft, 2016).

CLOUD SERVICE PROVIDERS AND SECURITY

There is no single consistent metric for comparing and assessing the suitability and quality of cloud Service Providers (CSPs). One valued source is that of Gartner, specifically its Magic Quadrant for IaaS. In 2018, there were only three leaders worldwide in this area: Amazon Web Services, Microsoft and Google. A few smaller CSPs exist such as Oracle, Alibaba Cloud and IBM (Gartner, 2018a). Due to the rapidly changing nature of cloud computing, greater focus needs to be the portability of systems and data. This means utilizing, where possible, open rather than proprietary frameworks and standards. Tools like Docker isolates and abstracts the software away from the CSP, making it easier to migrate from one CSP to another. In much the same way, Chef, Puppet and other automation and configuration tools can be used in a variety of environments.

When organizations adopt the cloud, much of their network, systems, application and data moves out of their immediate control and becomes the responsibility of the cloud service provider, something that clearly has profound implications for security, compliance and governance (Kale, 2014). The multi-tenant model of the cloud requires customers to trust providers, and not just with the orderly functioning of their operations but often with private data and intellectual property. The responsibility for security in the cloud is shared between customer and provider. With some of the security being the responsibility of the cloud provider and some of the security being the responsibility of the cloud customer. It is important that the customer understands, this demarcation line otherwise known as the “trust boundary”, since this involves having a good grasp of the scope of management and monitoring responsibilities. Moreover, the trust boundary changes depending on the service delivery model, the service level agreement and the provider’s approach to security (Mather, Kumaraswamy, & Latif, 2009).

Cloud security is still perceived by some as a barrier to cloud adoption. Most scholars believe CSPs run secure clouds (Scott, 2018) and this is likely true since large cloud providers can attract and retain the best security expertise and ensure that they adhere to best practice. The picture among consumers of the cloud customers, though, is quite different. A poll of IT leaders in European, Middle Eastern and Asian (EMEA) organizations found that 64% of IT leaders thought data security was the responsibility of the CSP. This is problematic as it suggests widespread misunderstanding and a lack of knowledge of the trust boundary, the line that demarcates the responsibility of the provider from the responsibility of the customer in cloud computing (Correia and Otiopong, 2017). In another survey of the top 10 emerging risks is “unauthorized access to sensitive or restricted information or the cloud provider is unable to provide access to information as a result of disruption to their own operations” (Gartner, 2018b).

With data being handled and stored by third parties, security, regulation and compliance considerations are vital. One widely-used standard is the Payment Card Industry Data Security Standard (PCI DSS), which applies to organizations that handle credit cards and specifies how personally identifiable information (PII) is stored and accessed. Another is the Health Insurance Portability and Accountability Act (HIPAA), which now designates providers as business associates of customers and therefore requires them to also be HIPAA compliant. These and other standards ensure operations are more secure but at some point, organizations also have to trust the cloud provider. Security is often cited as a barrier for

adopting the public cloud, and certainly in the past many customers have struggled with this (Carstensen, Morgenthal, Golden, 2012). This, though, is changing. As Rob Alexander, chief information officer of Capital One put it, “We can operate more securely on AWS than we can in our own data centers” (Krazit, 2015). The major issues for organizations are now instead a lack of resources and expertise (RightScale, 2016).

Organizations need not only specialist advice on the relevant legislation but also to make use of data classification framework so as to distinguish more sensitive data from less sensitive data. There is no standard that should be applied to all organizations since some are more tolerant of risk than others. The European Union, like many organizations, has adopted a cloud first strategy. This entails outsourcing IT delivery to a cloud service provider in order to reduce costs and enable innovation (Gleeson & Walden, 2016). As a result, costs switch from capital expenditure to operating expenditure, and as such makes it possible for organizations to adapt quicker to market conditions and organizational requirements.

FUTURE RESEARCH DIRECTIONS

Some scholars have expressed reservations and concerns that cloud computing both raises difficult questions related to security and relies heavily on a small group of large cloud providers, and that this threatens the essential openness and innovative nature of the internet (Anderson & Rainie, 2010). These kinds of questions do need to be investigated, as do how providers can best interface not just with customers’ devices but also with one another, because increasing numbers of customers’ systems and infrastructure utilize multiple providers’ clouds. These questions have not been entirely resolved, but what is clear, though, is that demand for and use of cloud services is rapidly increasing. Within a short time for instance few organizations will run their own email systems and most email will be stored in and accessed from the cloud. In addition, an increasing number and range of products from health monitoring implants to sensors in cars and buildings will rely on cloud computing.

One of the critical areas requiring scholarly attention is how government can create a sufficiently robust regulatory environment that will adequately protect customers, even though systems and data in the cloud traverse national boundaries and jurisdictions. These are as much philosophical as they are technical questions, but they demand urgent study and investigation. While many of the broad philosophical issues and challenges still need to be addressed, progress is being made with the development of approaches, frameworks and standards, including a unified cloud security taxonomy (Kumar & Goyal, 2019).

CONCLUSION

There is, strictly speaking, no such thing as “the cloud”. There is not one but many clouds, with providers aiming to make customers more effective and competitive through a wide range of services, including account management and billing, identity and access management, databases, developer tools, monitoring and a range of applications. Increasingly the cloud is mission critical for customers, whether these are individuals, small and medium-sized businesses or large corporations. It started mostly with test development environments and its use is expanding to increasingly diverse range of uses. The cloud increases access to resources that scale, but also masks even eliminates for customers much of the technical complexities and drudgery of running on premise infrastructure. Customers no longer need to manage hardware and licensing and have only to pay for the resources they use while being able to operate ef-

ficiently through the use of automation (Winkler, 2011). They can also immediately leverage large cloud providers' infrastructure to deploy applications easily and rapidly across multiple geographic regions. In 2014, there were twenty times more active VMs in the public cloud compared to 2011 (Bittman, 2015), making it clear that while the use of on-premise infrastructure and private clouds has increased, the greatest growth is from customers seeking to move new workloads to the public cloud.

When organizations adopt the public cloud, not only are they able to reduce the complexity and cost of operations, they also gain, through the provider, much greater flexibility, elasticity, and scalability. Storage, compute and networks can be "rapidly provisioned and released" (Mell & Grance, 2011) because interaction with the provider is minimal and operations are streamlined to maximize efficiency, including typically the use of standard service terms, service-level agreements (SLAs) and limitation agreements. This increased flexibility does raise challenges in terms of data security and access control because users store data and then share it with others who are not necessarily in the same trusted domain, but then staff managing on-premise infrastructure face the same kinds of challenges, often with a great deal less support from third parties. As one provider put it, the reason to move to the public cloud is "to lower costs, reduce complexity, and increase flexibility" (AWS, 2015). These factors will likely continue to drive growth in the public cloud over the next few years and beyond.

KEY TERMS AND DEFINITIONS

Cloud Deployment Models: The way in which cloud services are provision, for instance the private cloud, the public cloud, and the hybrid cloud.

Cloud Service Models: The distribution of responsibilities for technological requirements between customer and cloud provider.

National Institute of Standards and Technologies: A federal agency within the U.S. Department of Commerce that is responsible for measurement science, standards, and technology.

Service Level Agreement: A contract that defines the level of service the customer can expect from the cloud provider.

Trust Boundary: The boundary between the responsibilities of the customer and the responsibilities of the cloud provider.

Virtual Machine: A guest machine that is capable of sharing the same physical hardware with another guest machine and runs on a hypervisor.

Virtualization: The division of a computer into multiple execution environments so that one level (e.g. the physical) can be abstracted from another (e.g. the operating system).

INTRODUCTION

Poultry Sector

The population of the world is growing every year at an enormous rate. Continuous efforts are being taken to fulfill the basic facilities for a healthy life. The focus is to satisfy the food requirements for better and healthier food. Previously, poultry products like eggs and chicken were considered as agricultural products. There was poultry in the backyard for eggs and chicken on a small scale. Nowadays, the poultry products are accepted as a food item worldwide as the nutritive value of the poultry products is good. So, the eggs and chicken are gaining popularity as a healthy food. The poultry products are available at a reasonable price. Thus, poultry products are in more demand because of healthy quality food and low price. The processed food items from chicken are also becoming more popular all over the world. Also, there are dynamic changes in the urban lifestyle and food habits of the human and the per capita consumption of egg and poultry products has increased. To meet the increasing consumer demands, there is a need to enhance the production of good quality poultry products. Thus the poultry sector has huge scope to grow and market potential in developing as well as developed countries all over the world. The poultry sector has more opportunities for economic growth. So, with the idea of business, the poultry sector is becoming the poultry industry for economical profits. (Baines, 2004; Qualman, 2018).

The poultry sector is the most organized sector in animal agriculture and the fastest-growing sector in the Indian agricultural system. The poultry sector helps the agriculture system to rise with improved per capita income and economy rate. India is the world's third-largest egg producer and the fourth-largest producer of broiler chicken meat. India exports poultry and poultry meat products to various countries. The good market for poultry in Asia is Japan, Malaysia, Maldives, Indonesia, Singapore, etc. In the last five years, per capita, egg consumption has almost become more than double in India. The per capita poultry meat consumption has become 3.5 kg per annum. As the consumption of poultry product in most of the developed countries is more than 250 eggs and 20 kg chicken per annum, the poultry market is growing with many opportunities. (Chatterjee and Rajkumar, 2015; Hook, 2016).

With increasing demands for poultry products, there is a need for expansion and industrialization of this sector. The poultry products provide nutritive values to humans and safe for consumption. The

DOI: 10.4018/978-1-7998-3473-1.ch048

poultry sector improves the economic status of rural people. The future of the poultry industry is bright as the new opportunities and discoveries in different sections of the poultry industry are under research with the help of knowledge and challenges of this sector. (Abdul-Careem, 2015; Dhafr, 2006).

The research is going on to improve the production and quality of poultry products. Also, the scientists are working to reduce the contaminants, adulterants and to add more nutritive values to the chicken and other poultry products. With respect to the quality and health of chicken, the research work is going for improvement in the immunity of chicken and the production of healthy poultry products. The researchers are also identifying the new diseases of poultry; their causes, symptoms and treatments. There are some authorities to inspect and regulate the production of quality poultry products. The production in the poultry industry starts with the breeder farming then hatcheries. Once the hatch came out, the feed nutrition and growth of chicks is important. Then processing of poultry products like the collection of eggs and poultry meat processing is carried out. After that, the packaging and distribution of products to the customers are followed. The poultry products can further be converted into processed food and distributed to the end customers. This is the value chain in the poultry industry. (Chatterjee and Rajkumar, 2015). Figure 1 represents the exponential growth of poultry production with projected data.

*Figure 1. Representation of real and projected global poultry production
(Source: Qualman, 2018).*

CHALLENGES AND OPPORTUNITIES IN POULTRY SECTOR (Abdul-Careem, 2015; Hook, 2016).

The increasing production of poultry products is the need of an hour for over increasing demand of ever growing human population. This arouses some challenges in the poultry sector. These challenges can

be turned into various opportunities to develop this sector. The challenges can be associated with, some issues related to productivity, feed given to the chicken, storage and transportation of eggs and chicken, processing facilities and overall farm management. In spite of the challenges, the poultry sector should continue to grow exponentially over the years by innovative approaches like six sigma. There are many opportunities to improve the production of poultry products like improvement in farms, hatching units, processing facilities, storage, supply management, sanitation, skilled staff, etc. The challenges are explained in detail as below.

- **Productivity** Sometimes the facilities for production and procedures are being used to manage productivity are not inline. The low productivity of poultry is a challenge. The climatic variations in the farm can cause diseases to poultry as the mechanism to control climate are not proper. Automatic feed lines and temperature controllers can lead to improved productivity of the birds.
- **Storage Conditions and Transportation** If the poultry production is specific to a region then for the supply of eggs, live birds and chicken to other regions, good storage, and transportation facilities are the essential requirement. The unavailability of such facilities affects the quality of poultry and also creates a market imbalance. Storage and transportation of poultry birds in unhygienic conditions will also lead to low quality. Thus, the storage in cold chain, hygienic conditions should be taken care for poultry during transportation.
- **Availability of the Feed Ingredient and Quality of Feed** While considering the nutrition of birds, the supply of low quality of feed given to the poultry is becoming a big challenge and also opened lot many opportunities, nowadays. The feed provides all the nutritional values required by a chicken. If the quality of feed is not good, it will not help to produce healthier chicken with good quality of nutritional values for human consumption. So, the dietary supplements should be provided to poultry by taking into consideration of its nutritive values. There is growing competition between human and poultry for maize and soya especially. This leads to unavailability and increases feed cost.
 - **Processing Facilities** The processing facilities like feed processing unit, hatchery, other processing machineries, etc. should be provided in good hygienic conditions. The waste treatment plans should also be there in the poultry farm.
- **Farm Management** There are no specific guidelines provided by any authorities for the management of poultry farms. Farm should be managed by fully trained staff about the good quality production of poultry. The proper hygienic conditions should be maintained by expert staff by considering bio-security. The skillful and well-trained staff with knowledge of all processes and procedures will manage the farm well and meet the quality requirements of the chicken.

BACKGROUND

Hatchery Unit of Poultry

In poultry mostly domestic birds of various breeds of chicken; duck are kept for their eggs and meat. The eggs are kept in one room under artificial conditions to be hatched, that room is called as a hatchery unit. In India, there are more than 400 hatcheries. Out of which 160 are under Government authorization while rest others are operated by private sector.(Silva, 2016).

The veterinarian should be a technical person handling the hatchery unit. The hatchery manager is responsible for duties like to manage and co-ordinate all hatchery activities including managing the hatch schedule and other necessary records. The manager has to check and assure the quality of hatch including taking care of chicks with their packing, storage, and transportation. The manager of hatching unit should also have to manage animal welfare programs and comply with its policies, to plan budget. The manager has to maintain all the facility of hatchery unit with machines and equipments, to monitor cleaning and sanitation. The manager is responsible for supervision of all the activities and the employees for good quality production of hatching unit. (Rangoma, 2018; Ali, 2009). Figure 2 explains the flow of units in poultry.

Figure 2. Role of hatchery unit in poultry farming (Source: Darrin Qualman. 2018)

Hatchery Performance

There are some procedures to monitor the activities in hatching unit to control quality of hatch. These procedures are like fertility assessment of eggs, examination of debris of the hatch to check the developmental stages, monitoring weight loss of eggs during the incubation period, calculating chick yield, monitoring environmental conditions like temperatures, monitoring hatch window (Rangoma, M., 2018).

HATCHERY UNIT DESIGN (Rangoma, 2018; Silva, 2016; Linden, 2014; Samberg and Meroz, 1995)

The building of hatching unit should provide the best artificial physical environment so that the optimization of efficiency of conversion of a hatching egg into a live and healthy chick can be carried out under the process of artificial incubation and hatching. Figure 3 represents a design of hatchery unit.

Location and Size of Hatchery Unit

The location of the hatchery is important in relation to bio-security. The location should be proper and away from the poultry house and other poultry farms. The location should be isolated and should have its own separate entry and exit without connecting to other areas. The dimensions of the area of the hatchery depend upon the requirement of the supply of chicks and the number of eggs to be hatched in a single hatch setting. The separation of area for every stage of the hatch should be proper. The travel of eggs in the hatching unit should be shorter and in a single direction.

Hatchery Design

Figure 3. Representation of design and flow of the hatchery
(Source: Rangoma, 2018)

Required Equipment

- Incubators
- Egg setting equipment
- Egg transfer equipment
- Chick handling and washing equipment
- Climate control equipment

The designing and construction of the hatchery unit should be in a way that the process flow is in a single direction. The eggs should be kept for the hatching at one end of the unit and chicks should be removed from another end of the hatching unit. Thus, the eggs should move from one room to next room so that

no reverse travels of eggs till the chicks and packaging of chicks. This flow avoids the human movements and interference and thus maintains the bio-security. The unit of hatchery should have a change room, egg reception room, egg setting room, incubator room, egg candling room, hatching room, vaccination room, packaging room, washrooms, store room etc. Generator is an essential requirement of a hatchery unit for the continuation of electricity supply. Generally a separate room is maintained for the generator. There are guidelines about the specifications of dimensions, the material of construction and the way of construction of the hatchery unit room. The details of areas of rooms are as follows.

Change Room

A change room is crucial in a hatchery room as it assists to maintain a microorganism free the environment. It should be carefully constructed and located at the entrance and exit of the unit. All persons entering into the hatchery unit should undergo a spray or shower and should wear clean clothes or gowns in the change room. Also, while leaving the hatchery unit; everyone should again undergo the gowning process to their appeals.

Egg Reception Room

There should be the special door and room to receive eggs for hatching as no entry is permitted into the hatchery for the personnel delivering eggs. The room should have sufficient space for collecting the eggs.

Fumigation Room

The area of the fumigation room should be compact. A fan should be circulated for air and exhaust.

Egg Holding Room

The eggs collected for hatching should be stored in an egg holding room. Its temperature and air movements should be well maintained around 12 to 16°C.

Incubator Room

It is also called as a setter room. The incubator room should have good access to personnel to other rooms. The separation should be by sliding doors. The size of room depends upon the capacity of eggs to be hatched and the equipment to be used. In the incubator temperature is kept around 36.5 –37.5°C & humidity at 45– 55% with the careful arrangement of the eggs in hatching trays. Eggs are kept at an angle of 45° with the narrow end pointing down.

Egg Candling Room

When eggs are transferred from one room to another, candling should be carried out. The room should be dark for easy candling of eggs. They are situated in between incubator room and hatching room.

Hatching Room

The construction of the hatching room should be well and with sufficient space as hatchers are kept here in this room. The hatching room should have good fittings of doors, good ventilation system. Fumigation system should have ventilators to discharge fumigants. In the hatcher, the temperature is kept around 35.5 – 36°C with humidity at around 65 – 75%.

Chick Holding Room

The chick holding room should come after the hatch room. The temperature (24°C) humidity conditions should be well maintained to avoid the excessive drying of the chicks.

Chick Sexing Room

In this room the chicks are separated according to sex. This room should be very clean, warm, properly ventilated and maintained for all the conditions. The grading of chicks carried out in this room. The material of construction of the table should be such as that it helps in easy disinfection and cleaning.

Wash Room and Clean Room

The clean area is important in sexing and grading operations of chicks in the hatchery unit. So, there are separate rooms for washing of the chicks. Necessary facilities with high-pressure pumps should be available in the room. The trays are stored after the washing. They are stored in room next to wash room called as a clean room.

Packing and Dispatch Room

The packing and dispatch room should be with an adequate space and have entry from the sexing room, the incubator room and the hatching room. The vaccination also carried out in this room before packing. The separate area should be allocated for record keeping and storage in this room. The door of dispatch should directly open outside the hatchery unit. The area for vehicle parking and transfer of chicks should be separately maintained here.

Storeroom

The storeroom should have adequate space for storage of trays, trolleys, racks, packing materials, labels, etc.

HATCHERY OPERATIONS (Smith, 2004; Linden, 2014).

The sequences of hatchery operations followed in commercial hatcheries are,

1. Securing hatching eggs
2. Traying hatching eggs
3. Fumigation

4. Cold Storage
5. Warm eggs prior to setting
6. Loading of eggs
7. Candling
8. Transfer of eggs
9. Pulling the hatch
10. Hardening
11. Grading
12. Sexing
13. Vaccination
14. Chick delivery
15. Washing and cleaning
16. Disposal of waste

The operations carried out in hatchery unit for economical large-scale production of the chick. The quality of chick depends upon the eggs selected and kept for hatching. Figure 4 explains the steps in the hatchery unit.

*Figure 4. Sequential steps involved in commercial hatchery unit
(Source: Silva et al. 2016)*

Table 2. Sigma scale of defects

Sigma level (σ)	Defects (PPM)	Cost of low quality(% sales)	Level of competition
6	3.4	<10	World class
5	233	10-15	World class
4	6,210	15-20	High Quality
3	66,807	20-30	Industrial average
2	3,08,537	30-40	Industrial average
1	6,90,000	>40	Non-competitive

The six sigma levels also can be defined by the normal distribution curve. This curve represents the defect-free area between the upper specification level and the lower specification level. Figure 5 represents the normal distribution curve. (Jagdale, S., C., et. Al., 2018).

Figure 5. Normal distribution curve (Source: Jagdale et. Al. 2018)

FEATURES OF SIX SIGMA

The main idea behind the methodology is to measure the defects by using statistics, to eliminate the defects by using some structural plan and provide the improved process with increased profits. So, the features of the methodology can be summarized as follows. (Fuentes-Pila & Monroy, 2007).

- The six sigma improves process efficiency by eliminating errors and costs involved in the process.
- The Six Sigma method requires data collection with accuracy as this is a data-based approach to solve an issue.
- This methodology follows a multi-dimensional, structural strategic plan with defined the goals, roles, and responsibilities of personnel involved in the process.
- This methodology values customer needs and intensifies the customer satisfaction.
- This approach provides more profits to businesses in terms of the commercial aspect.

BENEFITS OF SIX SIGMA

The Six Sigma offers benefits to the process to reduce defects in terms to achieve customer satisfaction. It sets the goal for staff, provides an action plan, reduces the times involved in the activities of the process, and minimizes the errors and process variability. This methodology helps in achieving targets and improves the level of customer satisfaction. The methodology improves the quality of the product which reduces the cost involved in the production and provides more business profits. (Valles, et al. 2004; Jagdale et. al. 2018).

PROCESS AND STEPS OF SIX SIGMA

The process of six sigma can be explained as the steps involved in getting more profits from the identification of the process defects up to process improvement. The sequential flow of steps in simple and general terms is identification of the issues and problems in the process, analysis of the process, collection of statistical data, analysis of collected data, identification of the defects and variations, proposal of plan to reduce defects, application of plan, analysis of process with improved plan, measuring the cost profits and achievement of customer satisfaction. (Jagdale et al. 2018; Herron and Braiden, 2006).

The roadmap to achieve six sigma levels in a process is DMAIC. The term DMAIC is derived from Define, Measure, Analysis, and Control. These are the different and sequential phases for process improvement. DMAIC is the most common approach used and implemented by companies. Another approach used as a quality improvement technique is DMADV i.e. Define, Measure, Analyze, Design and Verify. The phases of DMAIC have discussed in detail below. (Nave, 2002; Jagdale et al. 2018).

Define (D Phase)

The define phase starts with the generation of project ideas. This followed by the selection of projects, finalization of a project charter, preparation of a high level of the process map.

Measurement (M Phase)

The measure phase finalizes the project and performance of standards. Then validation of the measurement system for the selected project is carried out. This followed by the current performance measurement of the project and determination of the gap or scope for improvement of the project.

Analyze (A-Phase)

The analysis phase collects all the statistical data required for project analysis. The review of the collected data is also carried out. Thus, the analysis of the root cause of defects is carried out in this phase.

Improve (I Phase)

The improve phase works on the generation and evaluation of solutions to resolve the identified defects. Then the selection of solutions and optimization of the best solution to the project is carried out. The implementation and validation of the best-chosen solution are also done in this phase.

Control (C phase)

The control phase works on documentation of the solution and benefits offered by the best-chosen solution. A well-documented project is finally handed over to the project owner in this phase.

After completion of all the steps, the project closure is carried out.

Table number 2 explains the phases, goals and tools utilization property of six sigma.

ORGANIZATION AND HIERARCHY IN SIX SIGMA

The format of the organization for the person involved in the team is defined with their roles and responsibilities. The sponsor authorizes the project. The coach acts as a consultant. The team leader monitors the work while team members actually work on the project. Based on roles, responsibilities, expert area and competence level of members, the belts are given. The green belt is for the team leaders and members who have an expert area in basic analytical and statistical tools. The black belt is for leaders who are trained for methodologies application and analysis. The Master Black Belt is for reviewers of the project. (Fonseca, 2014; Jagdale et al. 2018).

BASIC TOOLS FOR DATA COLLECTION

The use of tools facilitates the process in a more systematic manner. Many tools are available for quality check. Nowadays, the use of tools by service providers is becoming popular. Many organizations use the tools to identify and analyze the data. The data is analyzed in qualitative and quantitative approaches. The data is also interpreted for the identification and standardization of the best solution for the reduction of defects of a process. The tools should be simple, easy to learn, easy to use, easy to understand and easy to interpret the graphical representations. The staff should easily get trained in utilization of tools. Based on the type of the utilization the tools can be classified into three categories such as quality tools, management tools, and planning tools. (Krishnan & Prasath, 2013).

For the collection of statistical data, tools are being used. Some basic tools like a flow chart, Ishikawa diagram, Pareto chart, histogram, cause, and effect diagram, scatter diagram, control charts, etc. are used for data collection. The flow chart represents all the steps of a process. Check sheet prepared from the analysis and collection of data. Pareto chart used to find out the important root cause of defects. The Ishikawa diagram is also called as a fishbone diagram or five why diagram or cause and effect diagram.

Table 3. Phases and Tools in Six sigma steps

DMAIC Phase Steps	Goal	Tools Utilized
D - Define Phase	Define the project goals and customer (internal and external) deliverables. Define Customers and Requirements (CTQs) Develop Problem Statement, Goals and Benefits Identify Champion, Process Owner, and Team Define Resources Evaluate Key Organizational Support Develop Project Plan and Milestones Develop the High-Level Process Map	Project Charter Process Flowchart SIPOC Diagram Stakeholder Analysis DMAIC Work Breakdown Structure CTQ Definitions Voice of the Customer Gathering
M - Measure Phase	Measure the process to determine current performance; quantify the problem. Define Defect, Opportunity, Unit, and Metrics Detailed Process Map of Appropriate Areas Develop Data Collection Plan Validate the Measurement System Collect the Data Begin Developing $Y=f(x)$ Relationship Determine Process Capability and Sigma Baseline	Process Flowchart Data Collection Plan/Example Benchmarking Measurement System Analysis/ Gage R&R Voice of the Customer Gathering Process Sigma Calculation
A - Analyze Phase	Analyze and determine the root cause(s) of the defects. Define Performance Objectives Identify Value/Non-Value Added Process Steps Identify Sources of Variation Determine Root Cause(s) Determine Vital Few x 's, $Y=f(x)$ Relationship	Histogram Pareto Chart Time Series/Run Chart Scatter Plot Regression Analysis Cause and Effect/Fishbone Diagram 5 Whys Process Map Review and Analysis Statistical Analysis Hypothesis Testing (Continuous and Discrete) Non-Normal Data Analysis
I - Improve Phase	Improve the process by eliminating defects. Perform Design of Experiments Develop Potential Solutions Define Operating Tolerances of Potential System Assess Failure Modes of Potential Solutions Validate Potential Improvement by Pilot Studies Correct/Re-Evaluate Potential Solution	Brainstorming Mistake Proofing Design of Experiments Pugh Matrix QFD/House of Quality Failure Modes and Effects Analysis (FMEA) Simulation Software
C - Control Phase	Control future process performance. Define and Validate Monitoring and Control System Develop Standards and Procedures Implement Statistical Process Control Determine Process Capability Develop Transfer Plan, Handoff to Process Owner Verify Benefits, Cost Savings/Avoidance, Profit Growth, Close Project, Finalize Documentation Communicate to Business, Celebrate	Process Sigma Calculation Control Charts (Variable and Attribute) Cost Savings Calculations Control Plan

It asks the five why questions to get all possible causes. The control charts used to identify defects in a particular sample size. The scatter diagram represents the graph representing the process variable relation. (Nave, 2002; Jagdale, et al. 2018).

Some advanced techniques like software are also being utilized for accurate and efficient data collection. The use of software facilitates easy analysis and interpretation of statistical data. Softwares like

iGrafx Process, Quality Tools Chart Generator, Sigma Flow, Data Lyzer Spectrum, ARIS are in use. Some Lean and DMAIC online project tools are in use like Idea Management, Financial Management, Roadmap Templates, Document Management, and Employee Workspace. (Nave, 2002; Jagdale, et al. 2018).

DISADVANTAGES

The six sigma also has some disadvantages can be listed as follows. (Coronado, & Antony, 2002).

- The administration format may cause a delay in the process
- The need for well trained and skillful staff is essential
- The internal quality of the product may get hampered
- The barriers may come into a picture while practical applicability of the theoretical solutions and principles

APPLICATION OF SIX SIGMA TO HATCHERY UNIT OF POULTRY

The six sigma approach is a continuous process improvement methodology. The six sigma approach helps to achieve better output after utilizing the inputs and transforming through processing. In a hatchery, unit eggs are the input and chicks as the output. For the conversion of eggs to chicks, there is a specific process to follow. Any variation in the process and methodologies applied in the hatchery unit, leads to reduced yield i.e. number of chicks will be small or effects the quality of chicks. This lastly effects on customer satisfaction and business in economic terms. If the six sigma model applied to the hatchery unit, it helps to reduce defects in the process and improves the overall process with the supply of good quality of output i.e. chicks. (Coronado & Antony, 2002; Lucato, 2014).

To apply this methodology for a hatchery unit, the training to all staff involved in the process is essential. The hatchery unit employees may face the problem where caution needs to be taken. These problems can be a key project for six sigma applications to hatchery units. Applying a six sigma to a hatchery unit involves many activities, utilizes time, money and efforts of employees and sigma team members. The organization needs to define the objective to implement a six sigma approach and the quality improvement of the process. It should undergo DMAIC phases and utilization of tools to derive statistical data for improved solutions. The selection and implementation of an improved plan is an important phase. The training of staff for implementing six sigma derived solutions is necessary. (Lucato, 2014; Radha Krishnan & Arun Prasath, 2013).

In order to maximize the supply of disease-free day-old chicks from a hatchery unit, it is necessary to take care of various processes. The control of the staff and vehicle movement in and around the hatchery unit ensures the maximum hygienic conditions and maintenance issues related to bio-security. The single direction flow of eggs through the hatchery ensures the production of clean hatching eggs with an output of healthy day-old chicks. (Fuentes-Pila & Monroy, 2007; “*Sistema de produção ensuete*” 2016; Salloom & Al-Juboori, 2016)

The traditional and manual incubation and hatching processes are based on experience. The manual settings of machines, equipment, controlling climatic conditions are difficult and time-consuming processes. Automated hatchery units with sensors are easy to process and optimize hatchability. The six

sigma methodology helps in maintaining the hygienic conditions and bio-security involves the choice of suitable location and site of a hatchery unit, designing of hatchery building, maintaining the one-way flow of eggs through the hatchery till the production and dispatch of chicks and routine cleaning procedures. A proper ventilation system, a maintenance of temperature and humidity conditions help in hatching the eggs. The maintenance of the equipments and regular monitoring of the microbial load minimizes the contamination. The six sigma approach implementations to a hatchery unit can improve the process by resolving the issues which hamper the quality of chick. This increases customer satisfaction and more business. (Ketsarapong & Ketsarapong, 2016; *Sistema de produção enxuta*, 2016; Kaizen Institute, 2014).

CASE STUDY

A case study conducted by Kaizen Institute, India to reduce the egg damage showed improvement in the hatching process. It improves the hatching process from 90% timely delivery to 99%. (Kaizen Institute, 2014).

BENEFITS OF SIX SIGMA APPLICATIONS TO HATCHERY UNIT OF POULTRY (Salloom & Al-Juboori, 2016; Ketsarapong & Ketsarapong, 2016)

The benefits offered by six sigma methodology implementations to the hatchery unit of poultry can be summarized as follows.

- Improvement of bio-security issues as the cleanliness and hygienic conditions
- Reduction of damage to the eggs
- Improved hatchability of the eggs
- Improvement in the end to end flow of eggs i.e. receiving of eggs and dispatch of chicks
- Improved health quality of the chicks
- Improvement in on-time supply and deliveries of the day-old chicks without an error
- Improvement in the logistics systems like the transfer of eggs from farm to the hatchery, hatchery to customers and processing plant, farmers, etc.
 - Improved utilization of the reliability of an equipment
- Optimization of raw materials and inventory management
- Improvement in the capabilities of the employee as the goal is set.
- The discipline of an employee as roles and responsibilities are defined.
- Error-free recordkeeping.
- Overall improved performance.
- Increased business profits.

CHALLENGES

The challenges in applying the six sigma methodologies to the hatchery unit can face some challenges. (Coronado & Antony, 2002; Ketsarapong & Ketsarapong, 2016).

- Competition between different internal units in the same organization
- Time, money and focus requirements for optimization of a significant step of a process
- Lack of knowledge and training regarding the critical points of the process

FUTURE RESEARCH DIRECTIONS

To overcome the challenges mentioned above, there is a need of more researches so that the hatching process can be more efficient and beneficial in economical terms. The complete understanding, proper training and good execution of the sigma methodologies to a specific process are essential to achieve its objectives and goal. The major issues which arise during practical applicability of the process improvement methods in the hatchery industry like electricity failure, maintenance of temperature and humidity conditions, the hatchery infection need to be addressed. The more research needs in the area of sigma tools applicability and lean six sigma methods in the hatchery. Similarly, more researches are needed for six sigma methodology approaches in other units of poultry like cold storage, feed processing plant, egg powder plant, slaughterhouse, packaging plant, etc.

CONCLUSION

A hatchery unit is a production unit of disease free, healthy chicks from hatching eggs and their delivery and dispatch. The six sigma approaches in process improvement technology where with the help of statistical data the defects in the process are reduced. The six sigma approaches are focused on the improvement of the production process. For business profits in a hatchery unit, the design and management of workflow should be optimized. For improved production and good quality of chicks, the contamination should be controlled. The six sigma helps to maintain hygienic conditions in the hatchery unit as it is the prime requirement.

The application of a six sigma methodology to hatchery unit provides benefits like, decreased production cost, decreased time utilization in a process, improved quality of output i.e. supply of day-old chicks, improved productivity, reduced defects, and increased profits and at the same time meeting the level of customer requirements and satisfaction. Recent studies are carried out for the utilization of data collection tools to analyze and interpret the defects. These tools also help to propose new improved strategic plans for reduction of the variations in the process.

For the six sigma methodology implementations in a hatchery unit, it requires the training to the staff including management for process improvement, updated tools for data collection and systematic implementation of quality tools and improvement solutions. Though the applications of six sigma to poultry have some limitations, it will modify the process for improvements and more profits with good quality output. If six sigma methodology applications are implemented to other units of poultry like different farms of various breeds, feed manufacturing unit, feed processing unit, etc, then the poultry sector will grow exponentially with quality improvements. This will help the poultry industry to be a more organized sector, and business profits with excellence.

KEY TERMS AND DEFINITIONS

Bio-Security: It is nothing but preventive measures to lower down the transference of infectious diseases in poultry birds or other livestock.

Defects: It can be defined as the problems due to which the product or process fails.

Hatchery: It is a facility in which eggs are artificially hatched.

Incubation: It is a process of evolution of an embryo. In poultry, it is carried out artificially by maintaining the favorable temperatures and other conditions.

Poultry: The facility where homely birds are kept for their eggs and meat.

Process Improvement: These are the continuous attempts made for the betterment of the process or products by reducing defects and variations.

Six Sigma: It is a statistical data-based methodology for improvement of the process.

Designing a Business Analytics Culture in Organizations in India

Tanushri Banerjee

 <https://orcid.org/0000-0002-6060-3220>

Pandit Deendayal Petroleum University, India

Arindam Banerjee

Indian Institute of Management, Ahmedabad, India

INTRODUCTION

The environment in Indian organizations has changed dramatically in the past 10 years. With the advent of global operations, everyone is talking about digitization and measurements. For Analyst professionals, the job remains simple – Analysts tell stories. But their stories always match the data. Without data, there are only opinions where the person with the biggest title is always right. It has become very critical to be clear on when one has evidence and when there are only opinions because fact based decision making is the path to profitability and creating competitive advantage.

A recent research conducted by the authors concluded that Indian Organizations require heavy inputs in planning their Data Requirements and Analysis to synch them with Business Problem resolution. (Paper: Banerjee, 2017). Data Organization, Formats and Availability of data are real challenges and need careful consideration before any Methodology is applied. Although, Data Science in developed economies are more focussed on processing and methodology, there is a continuous strive towards creating a workforce that can be equipped to leverage both structured and unstructured data reservoirs driven by Better Data Organization and Technology to facilitate decision making. This has led to organizations in India create a Business Analytics culture within the company where top management believes that employees are empowered to perform better when they can confidently make data driven decisions within their respective domain of work.

BACKGROUND

A senior management team in an organization that is contemplating investing in an Analytics function may often times see such investments as a consequence of trying to organize the data overload from disparate sources. Lot of work has already been done across organizations to convert data into narratives and then communicate the story to the relevant client using visualization methods for superior engagement of the audience (Figure 1).

The authors have emphasized in their book (Banerjee, 2017) the critical factors affecting analytics adoption in organizations. The model described in the book suggests some key points that are specific to an emerging economy as shown in Figure 2. The top management of global companies, while contemplating on the need to invest into such an offshore operational unit is often unable to drive a turnkey solution and therefore begins by relying on local consultants who can explain the global benchmarks.

DOI: 10.4018/978-1-7998-3473-1.ch049

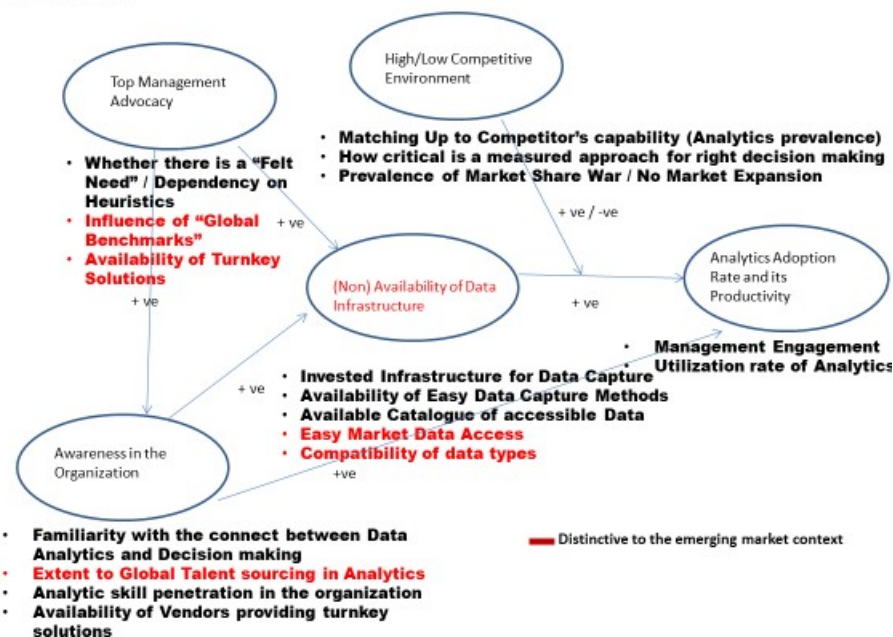

Figure 1. From Numbers to Narratives (Book: Banerjee, 2017)

There is a dearth of standardized data infrastructure due to legacy systems in place and compatibility issues. Adequate local resource is lacking and global resources may not be completely in sink with local needs for data, technology, culture and infrastructure.

Figure 2. (Book: Banerjee, 2017)

Critical Factors affecting Analytics Adoption in Organizations: with identified parameters distinctive to an emerging market context like India

RESEARCH METHODOLOGY

Building an analytics culture within organizations has been discussed in several forums, primarily with the advent of Big Data- data that is available in huge volumes; captured from multiple sources consciously by organizations or as part of an ongoing process; its availability in various forms text, audio, video,

image and online capture of data using sophisticated technology. The authors have used a case study to emphasize upon critical aspects that add value while deploying an analytics culture within an organization, with a focus on offshore operation. The case described below discusses some of these points and the methodology used for planning and implementing in a captive offshore operational unit in India.

CASESTUDY

A Global Bank's Consumer Lending USA – Operations in India

About

A global bank's top management has expressed the need to build a business analytics culture within their organization, across all office locations globally. It has presence in several countries across the world.

Its Consumer Lending (CL) arm has established an extension of its USA operations in the Global Service Center (GSC) in India in October 2019. The purpose of this CL unit is twofold:

- Support data management and analytical activities that serve as key inputs into CL's decision-making process
- Provide business insights emerging from consumer/market data analysis

The India based operation is expected to build an analytics culture and hence provide world class expertise in statistical and business analysis at a significantly lower cost. The objective for India based operation is to build a data management and analytical team in Consumer Lending to cost-effectively expand Credit Policy decision-making and ability to solve business problems. The unit is expected to have 46 resource persons across three broad functional areas (Credit Policy, CIM (Customer Information Management), and Marketing) in a couple of years time both by increasing output and enhancing the quality of work.

The four areas of focus in the next two years are:

- A. Hiring a senior Analyst to design the roadmap
- B. Designing a delivery-oriented organization structure
- C. Managing talent acquisition
- D. Managing skill upgradation and resource retention

The Roadmap Planned for Addressing the Focus Areas

As a first step Sonia Ray was hired as the senior Analyst. Sonia comes with 12 years of working experience with data management initiatives. Her experience has a mix of Business Acumen in the banking sector, good understanding of being able to plan Analytics driven initiatives (see figure 1), being able to work with technology teams to identify need for technology investments, an understanding of statistical models' outcomes, and being able to work with client teams to convert statistical outcomes to narratives that they can easily understand and implement. This touches upon the complete value chain of Business Analytics. Such a resource is difficult to find, hence she was brought into the company without much delay. After taking up the position Sonia formed a team consisting of end users, technology experts,

statisticians and analysts. As a first step, she and her team set out to gather relevant information which could provide insights about future talent demand in the Business Analytics roles in organizations in India. As a first step, she and her team studied and compared Research reports of 7 companies that provided a summary of research finding about the significance of building a skilled Analytics resource pool in India. Further, the analyst team compared the reports using text mining techniques in R software thus establishing similarity documented in the research reports. These reports describe the Analytics resource requirement by companies in India in the next 4-5 years. The seven company reports from which excerpts have been taken relevant to the topic of discussion in this paper are as follows:

1. Indian Workplace of 2022. Are Organizations ready for the future? (PWC, 2014).
2. The Age of Analytics. Competing in a data-driven World December 2016. Mckinsey Global Institute (Henke, 2016).
3. Analytics India Landscape in India 2017 study. (Imarticus Learning, 2017)
4. Becoming an analytics-driven organization to create value. (EY, 2015)
5. Rewriting the rules for the digital age. 2017 Deloitte Global Human Capital Trends. (Deloitte University Press, 2017).
6. How the new geography of talent will transform human resource strategies. (Oxford Economics, 2012)
7. An inside look on what influences the Indian Analytics industry. (Jigsaw Academy, 2017).

The wordcloud (Figure 3) and histogram (Figure 4) generated by text mining the contents of the reports using R software indicate the frequency of appearance of certain words in large numbers such as “data”, “analytics”, “their”, “more”, “big”, “talent”, “companies”, “business”, “skills”, “future”, “work”, “new”, “value”, “learning”. Certain words appear in greater numbers compared to others. The histogram represents the same information in the form of a chart.

Figure 3. Wordcloud

Figure 4. Histogram

Using the visual representation in both the figures, the analyst was able to communicate to the management that in India, organizations are considering analytics as a means to manage their big data in the next 4-5 years. New talent and skills in this domain are being more emphasized as learning platforms to create business value in companies. The analyst further made some suggestions as stated in section B, C and D.

Suggested methods for Designing a Delivery Oriented Organization: The initial plan, as suggested by Sonia, was to set up a “Ring-Fence” model with high degree of monitoring of projects by the local supervisory team (led by CL India Head) and functional managers at the US office and with some assessment on the appropriate choice of projects to be outsourced to India.

Based on a detailed analysis, recommendation was made for a “functional silo” model for the organization with the opportunity for competency specialization across locations as against a “consulting” model. There may be an opportunity to displace significant proportions of technology-driven activities and Credit Policy functions to India. Also, a separate R&D centre to address longer-term process development issues (analytics-centric) can be housed at the India office.

The “consulting” model (internal outsourcing) may not be appropriate for two significant reasons:

- Most functional areas have assignments that require close coordination between business/market experts and data analytics experts.
- Remote locations such as the India office will not match up to acceptable levels of onsite market/business expertise to provide meaningful turnkey solutions to problems.

The functional organization model was considered to be more appropriate by Sonia Ray and her team for the following 2 reasons:

- A) In the medium term under a functional organization model, US office teams will move closer towards the following roles:
 - 1) Drive business and market understanding in developing ongoing and new initiatives.
 - 2) Develop and manage mainstream projects that have strict timelines and provide research and analytics inputs.
 - 3) Support (and to some extent drive) new R&D projects that require higher level of statistical and analytic inputs.
 - 4) Provide overall strategic direction to CL policy making.
- B) India office teams will move closer towards the following roles:
 - 1) Support mainstream projects (under strict timelines) by providing routine data analytics planning and processing support.
 - 2) Drive a significant number of green field R&D projects that require high end technical modeling and analytics inputs
 - 3) Support New CL initiative building and Policy making with insights developed through data (primarily) and market understanding.

Managing Talent Acquisition: Sonia realized that in India there is high availability of “raw” analytical resources but with on an average little or no domain / business knowledge. This is both an opportunity and a challenge as well. The reason being that although the resource pool is very strong on statistical knowledge it lacks experience with large –scaled databases. Attrition is high mainly due to low switching costs (the next job is across the street) and no long term stakes in the organization. Key differentiation between jobs is salary – most other work conditions are similar (non-standard work hours, routine work content and fairly mediocre career progression plans). Sonia wanted to create and develop resource pool that are adept at Business Analytics and are valuable for the Global bank locally as well as globally.

Road Blocks and Threats to Attaining Objectives

The GSC, the local India based operations team’s mission and operating protocol is unfortunately not synchronized to the needs of CL. Threats to attaining a world-class Analytics organization in India are due to lack of clarity on the following dimensions:

- **Accountability:** The relationship between the local and global offices
- **Organizational structure:** Definition of teams and their deliverable, need for creating virtual teams.
- **Budget authority and accountability:** What can the local office employees decide independently without the global nod.

After detailed secondary research and understanding the requirements of the organization, Sonia and her team made the following suggestions. It was suggested that the Head of Analytics Sonia Ray (India) and other India team functional managers shall be responsible for developing a training plan for Business Analytics based decision making for each India-based resource and ensuring implementation. They shall provide ongoing feedback to direct manager(s) in the US on project progress for each resource and any recalibration of deliverables. Act as the local mentor for India based resources. Identifying analytics

Table 1.

Key Area	Current Situation	Next Steps
Define roles and responsibilities of GSC	Unclear definition and roles of GSC	Senior management to negotiate with GSC global head to define a workable operating model for Bangalore operations
Designing delivery oriented organization	Evolving a satellite operation to Home Office	a) Complete assignments of projects to 90% of workforce b) Complete plans for new organization staffing requirements
Managing talent acquisition	Initiated Phase I recruitment process	a) Complete Phase I recruitment to build strength to 46 resources b) Enable team constitution and mentoring processes c) Complete basic training module for all new hires d) Initiate “Head Start” program for ongoing recruitment e) Complete review of compensation plan f) Develop plans for Phase 2 recruitment g) Complete infrastructure plan for Phase 2 recruitment
Managing Skill Upgradation and Employee Retention	Policies built for call center operations environment	a) Develop retention incentives in compensation program b) Enable team constitution and mentoring processes c) Initiate progression planning process for new hires at Bangalore and implementation of same on Phase 1 hires

development needs of local resources and ensuring early implementation of corrective action – specifically on parameters that directly affect integration of teams across remote offices.

The Functional Managers in US office will be responsible for Prioritizing Project delivery and specifying end deliverables (in consultation with the India Senior team members) that can be driven

by Business Analytics acumen. They shall conduct periodic project monitoring reviews along with the India senior team member. Additionally identify analytics training needs of its resources and developing a plan with the India team members on implementation. Flag the India Senior team on possible issues affecting long term integration of teams.

An action plan prepared by Sonia and her team is shown in Table 1.

CONCLUSION

The case study represents the challenges faced by many organizations while deploying Analytics operational teams in India. Here in particular, the case highlights the challenges for a global organization that is implementing a captive offshore operation in India. With experience and growing resource pool in India, such initiatives are developing into processes that can be replicated across organizations, albeit customized specific to the organization needs.

Future Research Direction

Business Analytics is an evolving area of study as regards to its application for data driven decision making in organization. The case described in this chapter has discussed how a business analytics culture can be created in an offshore operation of a global firm. In general Business Analytics is led by an objective to find specific insights or test and validate some hunches that the organization and its managers may have using appropriate tools and techniques. Various organization models of Business Analytics have emerged depending on utility and dependability of business on Analytics outcomes. The outcomes are presented using appropriate visualization methods supported by story telling methods. Ample opportunities exist in studying how organizations have evolved in adapting Business Analytics for their sector specific needs. Future research can be carried out in this area. Additionally, it will be interesting to determine the difference that exists in deploying Analytics culture in developed versus emerging economies across global organizations.

KEY TERMS AND DEFINITIONS

Business Analytics: It is the process of working with factual information in organizations, using suitable tools and techniques to identify the nuggets of wisdom (insights) from them that can have direct impact on influencing good decision making.

Consumer Lending: It refers to the process by which a consumer takes loan from a bank. It is the category of lending centred around individual or household customers such as home loans, automobile loans, personal loans.

Data Science: With the increase in the amount of data captured by organizations, the various forms of structured and unstructured captured and the speed and frequency of it, significance of data science has increased over time. Data science is a methodical form of integrating statistics, algorithms, scientific methods, models and visualization methods for interpretation of outcomes in organizational problem solving and fact based decision making.

Global Services Centre: It means a central point of offering operational services for an organization. In this case, it refers to the local operations of the Global bank extended at the offshore unit of the bank in India.

Offshore: Move some of the organization's functions to a different geography than where the head office is located.

Text Mining: It refers to analysing large quantities of unstructured textual data using data analytics methods for relevant outcomes.

Wordcloud: It is usually an outcome of visualization method used for analysing textual data. It is a pictorial representation of frequency of occurrence of terms in textual documents, thus highlighting the ones that have maximum and minimum occurrence. It aids organization decision making and sensitivity analysis.

Review and Evaluation of Systems Supporting Data Journalism

INTRODUCTION

In recent years, a new form of journalism has developed a strong dynamic: Journalism based on data. An important factor in its success is the availability of data from many public bodies and international organizations as part of the movement of open data worldwide. This form of journalism is based on the creation of stories that are based on data (storytelling), which are presented with attractive visualizations. Journalism of this type is practiced by both professional journalists and ordinary citizens (citizen journalism). The success of the move is so great that technologies and applications that support it have begun to emerge. Applications supporting data journaling have been developed in a wide range of domains that serve specific purposes in the data processing process and satisfy a wide range of users. Data processing involves many activities, but the key steps for completing the process are: data collection and cleaning, analysis and visualization, and ultimately the publication of the story. Although technologies are in a period of mature productivity, their evaluation is an area lagging in development. It is a fact that lack of evaluation based on a reliable methodology is evident in the literature. Finding a suitable methodology for this purpose is particularly important in order to (a) evaluate systems supporting data journalism resulting in a specific ranking of potential, and (b) make it easier for the user to choose the application that best suits his / her requirements and cognitive level. This study will attempt to evaluate specific applications with the assistance of appropriate methodology. A comparative evaluation of 9 applications related to the visual imaging component was attempted based on a methodological approach with usability and functionality criteria. The aim of this study is to provide a quick evaluation method, open to proposed improvements and further refinements, in order to establish a framework for qualitative assessment of data journalism applications.

BACKGROUND

A system's evaluation is the process of testing and validating whether the system achieves its predefined goals and in what degree. Although in literature there are several qualitative and quantitative techniques

DOI: 10.4018/978-1-7998-3473-1.ch050

proposed for different kinds of systems, there is not yet enough research for data journalism systems evaluation, so a goal for the area is for an evaluation framework to be established. Relative background can be found in related areas (e.g. information visualization, HCI), while the most suitable criteria for the proposal of such a framework are: functional and usability features.

Yi et. al. (2007) have collected the techniques from various research papers by creating a classification for InfoVis (Information Visualization) related to the interaction techniques. The following three classifications focus on interaction techniques, while the fourth refers to the tasks of the system's user, i.e. it focuses on his/her goals without paying attention to the interaction. The four proposed classified techniques with their related research work are:

Low-level Techniques. Buja et al. (1996) classified the interaction techniques into three classes: *Focusing*, *Linking*, and *Arranging* views. Chuah & Roth (1996) summarized a set of basic visualization interaction (BVI) operations: *Graphical* operations, *Set* operations, and *Data* operations. Dix & Ellis (1998) condensed the different ways in which interactivity adds value and resolves conflicts in representation: Highlighting and focus, accessing extra information – drill down and hyperlinks, Overview and context - zooming and fish-eye views, Same representation / changing parameters, Same data / changing representation, Linking representation – temporal fusion. Keim (2002) proposed that in addition to the visualization technique, it is necessary to use some interaction and distortion techniques for an effective data exploration: Dynamic projections, Interactive filtering, Interactive zooming, Interactive distortion, Interactive linking and Brushing. A categorization of interactions can also be found in Wilkinson (2005). Interaction techniques are classified into seven categories: Navigating, Manipulating, Brushing and linking, Filtering, Rotating, Transforming, Animating.

Interaction Techniques. Tweedie (1997) considered interaction techniques based on the following taxonomical dimensions: Interaction types (manual, mechanized, instructable, steerable, and automatic) and Directness (direct and indirect manipulation). Spence (2007) concerned with taxonomy interaction techniques as follows: continuous, stepped, passive, and composite interaction.

Interaction Functions. Ward & Yang (2004) proposed a framework for interaction techniques, identifying distinct classes and shared concepts. The classification of interaction operations follows:

- interaction operators
- interaction operands & spaces, data value-spaces, data structure-space, attribute-space, object-space, visualization structure-space
- interaction parameters

User Tasks. Concerning the taxonomies of user tasks, Zhou & Feiner (1998) proposed that visual tasks serve as an interface between presentation intents and low-level visual techniques, they can be characterized along two dimensions: visual accomplishments and visual implications. The set of features which describe various aspects of visual organization is: Visual grouping, Visual Attention, Visual Sequence, Visual Composition, Visual Signaling. Finally, Amar et al. (2005) present a set of ten low-level analysis tasks such as: Retrieve value, Filter, Compute Derived Value, Find Extremum, Sort, Determine Range, Characterize Distribution, Find Anomalies, Cluster, Correlate.

Yi et. al. (2007) bridge these approaches and propose an evaluation scheme based on three axes for evaluating interaction models:

1. Descriptive power: The ability to describe a significant range of existing interfaces.
2. Valuable power: The ability to evaluate alternative design modes.

3. Generic power: The ability to offer help to design new interfaces.

Few & Edge (2012) list the features that visualization tools should support in certain categories: Visualizations, Interaction, Multi-Chart Displays, Statistical Calculations, Speed of Response, Data Access and Integration, Output and Content Management, Platform Options, Ease of Learning and Use, Programmability, Advanced Features.

Another approach of evaluating visualization software by Atwood & Reznik-Zellen (2018) is based on the use of Rubrics, that is, tables that contain characteristic criteria that are graded on a 3-level scale. The Rubric of writers is based on 13 criteria in order to evaluate technologies in a holistic high-level way. These criteria are divided into two categories with functional and usability features (as shown in detail in Table 1). The score ranges from 0 to 3 with 0 meaning poor, 1 modest, 2 good and 3 excellent.

For the purpose of the evaluation in this article, the approach of Atwood & Reznik-Zellen (2018) was chosen due to greater applicability to data visualization technologies. It can be broadly applied to technologies that primarily target interactive graphs, maps (mainstream), networks or combinations of them, on which we will focus on this study.

We have added one usability criterion in the original approach (No. 14 - Table 1), which refers to the ability to store on a cloud-based platform (cloud service) with some temporal/spatial restrictions and the possibility of visualizations privacy settings. This means we can discern the difference between the storage of an image file format or other type and that of cloud-based storage that is individually rated with spatial/time constraints. In this category, if the manufacturer of the application did not refer to time or storage limitation, it was considered that there is no such limitation.

REVIEW OF SYSTEMS SUPPORTING DATA JOURNALISM

Our goal is to evaluate tools that help a journalist support their own story with the means provided by technology. Because technologies are enough and cover different sectors in the field, often overlapping with each other, we have used some inclusion/exclusion criteria for the systems to be evaluated. The following software systems were selected on the basis that a data journalist should have no specialized programming skills, but he can use a tool that can learn easily, in a short time in order to bring the story to his public in the best possible way. The inclusion / exclusion criteria are as follows:

- Tools that need code input to create visualizations were excluded (e.g. google charts).
- We included tools that could be used for a reasonable amount of time without restrictions on their basic functionality either as a desktop version or as web-based applications.
- Applications to be evaluated could be made available without any financial consideration for use by interested parties for some time.

The evaluation will be done separately for each application with a description of its purpose, a brief explanation of its functions, some observations we made when testing each one in individual attributes, and the score in the attributes selected with the individual comments in each category. To control entry capacity, we used 3 xlsx files of about 5 MB (120000 lines), 9 MB (240000 lines), 30 MB (865000 lines). The evaluation of data journalism systems has been conducted by the first author of the article by testing the tools on certain tasks (specifically the creation of interactive charts, maps and network graphs) for producing journalistic stories, using the aforementioned datasets.

Next, we present a short review for the applications being evaluated in the present article: Tableau, Gephi, Cytoscape and web-based applications Datawrapper, Plot.ly, Datavisual, Infogram, Datacopia & Filtergraph.

1. Cytoscape (Desktop Version 3.6.1)

Purpose of use: An open source software platform to visualize complex networks for each type of data.

Description: Although originally developed to assist research in biology, it is also used in other areas of network analysis (Shannon et. al., 2013). It is designed to analyze and visualize large-scale networks. The input accepts a variety of file formats (sif, nnf, gml, BioPAX etc.). The network can be created either sequentially by the user with the possibility of inserting pictures, shapes or text frames, or automatically by the system by entering data from a table where the user guided by the interface defines the details of the network. Tools for handling visualization network include functions such as scale, align, rotate, distribute and a variety of algorithms for graph layout. A feature of the menu is the access to available-to-install apps that perform specialized functions. Filtering can be applied to select a subset of nodes and edges that meet certain criteria Network layout algorithms support various representations with a variety of features. The publication of visualization is supported by several options.

2. Datacopia (Web-Based App)

Purpose of use: Web application for making interactive charts.

Description: Data input is done via URL in csv or tsv format, uploading the user file in csv, tsv, txt, xls, xlsx and finally by typing or pasting data to a form denoted by commas. Visualization supports many kinds of charts (including maps). The interface automatically calculates a number of charts of various types such as scatter plots, function plots, histograms, spider charts, etc. (in our case, 189 charts) that are displayed to the user. The user can choose a chart of his / her choice that can interfere with very basic formatting parameters. Saving is performed in low resolution png. The distribution of the chart can be done through Reddit, Google+, Pinterest, Twitter, Facebook with rudimentary cloud storage support, but without interactivity and the ability to create a personal account.

3. Datavisual (Web-Based App, Beta Version)

Purpose of use: Web platform for the design of selectable charts through a collection of interface templates.

Description: The user selects the type of chart he/she wants and through the appropriate filters he/she formats the chart. The design is aided by various tools such as sliders, color pickers, on/off function buttons and text boxes. The data input is done with an excel, csv or tsv file and through a special menu he can interfere with the degree of interaction of the chart through tools such as display of information when the pointer is at some point (hover display, hover label size, etc.) and animation techniques for chart presentation (Bar duration, Bar delay, Label Duration, etc.). Storing is done in low-resolution jpeg format while other file types and web embedding are supported after upgrading the account. Only the English language is supported while the output can be saved in low resolution jpeg. No support material is available in any form, and no information is provided about the hosting conditions of the charts on the server site.

4. Datawrapper (Web-Based App Version 1.20.0)

Purpose of use: An online application of interactive charts and maps.

Description: The application has been created with the participation of a group of journalists who have worked in major media such as the New York Times, NPR, Deutsche Welle, Bloomberg, etc. It is available in a variety of versions from the trial one (free of charge and it is the one we tested) up to a business version. The free choice has the limitation of 10000 tests; the full functionality of the application (output formats and styling, etc.) is not supported, while canceling the registration can be done without limitations though the fate of visualizations after the cancellation is not specified. The user does not need a cognitive background and the result comes out through a few guided by the application steps. Account creation is required to store and share charts. The result is finalized through 4 directed steps that are: upload, check & describe, visualize and publish & embed.

Statistical analysis is not supported except a graphical trend line with 6 defaults in the Refine tab. Output formats are not supported except storage on a cloud-based platform. The version is available in 15 languages.

5. Filtergraph (Web-Based App)

Purpose of use: Web platform drawing charts and maps.

Description: Filtergraph is an interactive web-based tool for displaying large data sets. Although originally designed to meet the needs of astronomers in a wide range of projects, it can be used to manage data in any situation where large-scale visualization of data, including academic research and data-based publishing, is required. The input accepts a variety of file formats. Initially, the user has the ability to specify names and restrictions of access to the content of the portal (filtergraph.com/NameOfPortal), and also it is possible to delete all of its saved content. He can invite readers or registered users via mail using a link with view or view and edit permissions. The interface contains column data filter and the possibility to highlight them, undo function and 10 graph options (map, scatter, line, error bars, histogram, stacked histogram, heatmap, surface map, bar chart, pie chart). Storing is done in 6 different formats and a statistical description function is provided. There is a difficulty in displaying categorical data (setting capability, displaying the desired number on the axes), while hover mode is not supported.

6. Gephi (Desktop Version 0.9.2)

Purpose of use: Open source software for exploring and manipulating networks.

Description: The application runs on Linux, Windows and Mac and requires installed version of Java 7 or 8. Data entry is done with a spreadsheet, other types of graph files or via online connection to MySQL database, SQLite, PostgreSQL etc (Bastian et. al. 2009).

Gephi uses 3D graphics to showcase large networks in real time, speeding up their exploration. Provides individual functions that facilitate the import, visualization, filtering, fixation, spatial representation and output of all types of networks. The user interface consists of workspaces where individual tasks can be performed. Nodes or edges can be obtained manually or by using the filter system. Filters can choose nodes or edges with boundaries, range, and other properties. The frames of the filters are designed in a chain way so that the next frame accepts as input the output of the previous one. The graphics elements accept as input a group of nodes and modify the visualization

parameters. The architecture of the system supports graphs whose structure or content varies over time. A data source can send network data to the potential controller at any time and visualize the result in real time. Architecture is interoperable. Nine languages are supported including English.

7. Infogram (Web-Based App)

Purpose of use: Web platform for charting, maps and infographics.

Description: Use of the service requires a simple registration or use of a google / facebook account. Data can be imported using excel spreadsheets, cloud services like dropbox, OneDrive or json files. An open data finder is supported. The interface enables the creation of some type of infographic, chart or map. In the infographic option the user can select one of the available templates, add title and text, adjust the font, align, and other options that text editing software offer. In the field of charts, there is available a variety of types of charts with color adjustment functions of their size, with the addition of the labeling of axes and the appropriate range of values to the axes. The construction of maps in free version is only supported in two types: Global and United States. The result can be publicized using a hyperlink in social media or embedded on a website or blog. Five languages are supported.

8. Plot.ly (Web-Based App)

Purpose of use: Web platform creating charts and control panels (dashboards).

Description: The platform is used after signing up with a Google account, twitter, facebook, GitHub, or simple email. Data entry is done in csv, xls, xlsx, via URL, or linked to a SQL platform. A diversity of chart types is supported, which are divided into 6 main categories. Basics (scatter, line, bar, Area, pie), stats (histogram, box plot, 2d histogram heatmap, 2d histogram contour plot, parallel coordinates), scientifically (error bars, heatmap, contour, ternary plot, carpet, Sankey), Maps (Chloropleth, Atlas maps, satellite maps), 3d (3d Scatter, 3d line, 3d surface, 3d mesh), economical (range slider, candlestick, OHLC, animations). It supports filtering in the dataset with immediate overview of the changes. A wide range of formatting functions is supported. Storage in the chart and the data has privacy settings.

9. Tableau Public (Desktop Version 10.5)

Purpose of use: A software for data analysis through interactive and shared visualizations depicting trends, variations and density of data in the form of a plurality of graphs, charts and maps.

Description: The basic steps for creating a data processing report include:

1. Linking to a data source (files, SQL databases or other types of cloud-based platforms).
2. The choice of dimensions and measures (dimensions are categorical data while the measures are numerical) for the analysis.
3. Applying visualization techniques using filters, grouping, color management, captions etc.
4. Creating multiple worksheets that create different views on the same or different data.
5. Create and organize a dashboard that contains multiple worksheets that are linked to each other.
6. Creating a story based on a sequence of worksheets or dashboard that work collaboratively to transfer information.

Also, a statistical analysis of the data as well as a wide range of operators, functions and calculations in numbers, strings and dates is supported.

EVALUATION OF SYSTEMS SUPPORTING DATA JOURNALISM

Table 1 shows the evaluation criteria (Rubric) and summary tables 2 and 3 show the comparative evaluation of the applications with the corresponding score that resulted after their evaluation by the first author of the article. Figure 1 shows the bar graphs of the overall comparative evaluation.

Figure 1. Overall comparative evaluation

Total Evaluation

Desktop applications due to more and more powerful features show higher scores. The web-based applications generally exhibit lower levels of usability and functionality features as described in detail.

Note that the joint evaluation in Tableau public, Plot.ly & Datawrapper was made independently of that of Atwood & Reznik-Zellen (2018) with some differences in individual scores in the 13 common evaluation criteria. The other tools were evaluated by the author without any other similar assessment in the literature. A comparative table of scores is shown in Table 5. In Table 5, yellow color depicts our evaluation, while the pink is that of Atwood & Reznik-Zellen (2018) and the shades of green show the differences in the score. The dark shade is a difference of 3 points, the middle shows a difference of 2 points and the low is a difference of 1 point.

We list the pivot Table 4 with the scores per application.

Table 1. Modified evaluation criteria (Rubric)

No	Category	Feature	Poor (0)	Medium (1)	Good (2)	Excellent (3)
1	Usability	Ability to handle	There is no control of the output design	Low handling capacity. (modification of one or two elements)	Some ability to handle. (modification of many items but with limitations)	Full control of all aspects of the output design.
2	Usability	Support materials	There is no documentation.	Insufficient documentation with little information about key features	Almost sufficient documentation. It leaves out some features.	Well documented. Available technical support (online chat, troubleshooting, videos, webinars, etc.
3	Usability	Ease of use	Graphics and hyperlinks are not labeled; fonts are difficult to read, poor navigation, need of a cognitive background, that is, not accessible to all users.	Some available tags, navigation is not clear.	Many tags available, navigation is simple	Graphics and hyperlinks are well-marked, fonts are legible and do not require extensive knowledge.
4	Usability	Learning time	It takes a long time (> 5 hours)	It requires a moderate time (1 hour - 5 hours)	It takes less than 1 hour. (from 10 minutes to 1 hour)	It requires a minimum of time. (totally intuitive or less than 10 minutes)
5	Usability	Making use of previous knowledge	Previous experience with other software, code, or previous versions is required	Previous experience with other software, code or previous versions is recommended. Quite intuitive.	It requires little experience with other visualization platforms	Totally intuitive
6	Functionality	Processing power	Only accepts files smaller than 5MB.	It can accept files of limited size.	It can upload/download file sizes of any size with a login	User can upload any file size without limitations
7	Functionality	Login requirements	A connection is required for all functions.	A connection is required for most functions.	A connection is required for some specialized functions but access is possible for routine functions.	No connection is required for full function.
8	Functionality	File type requirements (Input)	Only accepts one or two types of files in specific formats.	Accepts only a few types of files	Accepts multiple types of files of various types.	Accepts all file types.
9	Functionality	Cost for “full” version	High cost. (over \$ 100 / year)	Medium cost. (between \$ 100 - \$ 20 / year)	Low cost. (below \$ 20 / year)	Totally free.
10	Usability	Built-in analytics	No analysis supported.	Available basic mathematical functions.	Many functions available.	Complete range of available analysis methods.
11	Functionality	Output	Output is not supported.	Limited output supported (1 or 2 formats you can export), low resolution.	Some supported output-either with many file types, but with limited numbers or with many downloads available with very limited output formats.	Many formats and unlimited downloads, high resolution.
12	Functionality	Data collection	It gathers and maintains all information that has been uploaded, allows third parties access to information.	It collects personally identifiable information.	Collect cookies.	It keeps little or no information.
13	Usability	Aesthetics	Minimalist style, few options, limited color palette, limited fonts...	Minimalist style but some flexibility, more charting choices, or style options.	Various style choices and chart types.	Many style options available, such as color, font, chart type, etc.
14	Usability	Save on a cloud-based platform for public sharing with or without limitations	Paid or no storage capability.	Free for a period of time or limited to the number of visualizations without any privacy settings.	Free for some time or with a limitation of the number of visualizations with privacy settings.	No limitations and privacy settings.

Table 2. Comparative evaluation of apps: Cytoscape (3.6.1)/Datacopa/Datavisual/Datawrapper/Filtergraph

Evaluation Feature	1. Cytoscape (3.6.1)	2. Datacopa	3. Datavisual	4. Datawrapper	5. Filtergraph
Ability to handle	Full control of all aspects of output design. (3)	Insufficient control in the output design of visualization with interference in some elements. (1)	The user has partial control over the final output of his / her work mainly in formatting the chart. (2)	The user has partial control over the final output of his work through guided steps. (2)	Some ability to handle. (Modification of many elements but with limitations). (2)
Support materials	A user manual is provided with detailed documentation, online presentations, FAQs, mailing list support (3)	Only one demonstration of the basic charts in a gallery without explanations is provided. (0)	Documentation is not supported in the basic version. (0)	A knowledge base with a search engine is supported with relevant articles on application functionality and a blog coordinated by the production team with news, updates and ideas from the community. (2)	A video and a help page are provided with detailed information about the functions. (2)
Ease of use	There are many available and comprehensible labels to facilitate navigation. (2)	Few labels without additional assistance to help navigate. (1)	Accessible to the beginner user with direct result through two steps: selecting & importing data. (2)	Very good UI, user friendly, with the ability to instantly track the changes made (3)	It takes a lot of time to familiarize the novice user with the interface menu. (0)
Learning time	It takes a long time to familiarize the average user with the capabilities of the program. (0)	Minimum time is required to visualize the data. But it takes time for selecting the appropriate graph that satisfies the user. (3)	Minimum time is required < 1 hr to fully enrich the novice user with the application interface. (2)	It requires time < 1 hr for a novice user to familiarize with its functionality through strictly defined steps. (2)	It requires moderate time. The user must experiment with the capabilities of the application in order to achieve the desired result. (1 hrs - 5 hrs). (1)
Making use of previous knowledge	Graphics of the interface are quite functional but for the navigation menu the previous experience with similar software can reduce the learning time. (1)	The construction of the diagrams is automated with few intervention options by the user so it can be described as intuitive. (1)	Intuitive to a great extent without requiring previous experience from similar applications. (3)	Intuitive to a great extent, since possible actions of the user are guided by the interface diligently. (3)	Previous experience with other software or earlier versions is suggested to allow the user to quickly use it. (1)
Processing power	Editing the graph binds memory to the user's PC, so the performance depends on the characteristics of RAM and the system graphics card. (3)	We attempted to upload the 5MB file into the application without success. (0)	A 5MB file slows the browser to a large extent, so it does not finish loading the file within a reasonable amount of time. (0)	A 5MB file is significantly slowing the browser (firefox quantum 63.0.1 64 bits), so the upload of the file is not completed within a reasonable amount of time (0)	We uploaded a 30MB file (approximately 860000 lines) successfully. (2)
Login requirements	No connection required for full operation. (3)	No connection required for full operation. (3)	Editing and formatting are done by connecting to a user's personal account. (0)	Editing and formatting are done by linking to a user's personal account. (0)	A connection is required for all functions. (0)
File Type Requirements (Input)	Although it accepts various types of files, ODF formats such as .ods spreadsheets are not included. (2)	Accepts files such as .csv, .tsv, .txt, .xls, .xlsx. (1)	Formats such as xls, csv, and tsv are supported (1)	Formats such as xls, csv, google spreadsheets, and a csv file hosted on another server are supported, with the ability to automatically refresh the file and make changes in the visualization from time to time for the month following publication. (1)	It accepts files of various types such as ASCII text files (space separated, comma separated, tab separated, and fixed length), Microsoft Excel files (*.xls, *.xlsx), SQLite files (*.sqlite), VOTable files (*.vot, *.xml), FITS files (*.fits), IPAC files (*.tbl), Numpy files (*.npy), HDF5 files (*.h5) (2)

continued on following page

Table 2. Continued

Evaluation Feature	1. Cytoscape (3.6.1)	2. Datacopia	3. Datavisual	4. Datawrapper	5. Filtergraph
Cost for “full” version	Free. (3)	Free. (3)	Free for basic version and for full (pro) 15 \$ / month. (0)	Free for single version with a limit of 1000 views for 1 user while for full (custom) 279 € / month. (0)	Free. (3)
Built-in analytics	A complete set of metric statistical analysis is available such as: AverageShortestPathLength/ BetweennessCentrality/ ClosenessCentrality/ ClusteringCoefficient/Degree/ Eccentricity/IsSingleNode/ NeighborhoodConnectivity./ NumberOfDirectedEdges/ NumberOfUndirectedEdges/ PartnerOfMultiEdgedNodePairs/ Radiality/Stress/ TopologicalCoefficient/ EdgeBetweenness. (3)	Not supported. (0)	Not supported. (0)	Only graphical display of trend lines with 6 presets (in the Refine panel with application in scatterplots type diagrams). (1)	Many available functions such as: Single variable statistics (percentiles: 5 th , 10 th , 25 th , 75 th , 90 th , 95 th , Minimum, Median, Maximum, Mean, Standard deviation, Variance, Sum), Two-variable statistics: (Linear regression, Quadratic regression, Cubic regression), Correlation matrix. (2)
Output	Many formats and unlimited downloads, high resolution. (3)	One type is only supported. (.png) (1)	Public sharing is supported through a hyperlink to the user's account in the application and low-resolution .jpeg. (1)	Only publicly shared hyperlinks to the user's account in the application or integration with code on a personal site are supported.	Many formats and unlimited downloads, high resolution. (3)
Data collection	When running Cytoscape, the usage statistics are recorded with the date, time, and IP address of the workstation running Cytoscape. This recording can be disabled when installing Cytoscape. (3)	It gathers little information for statistical purposes. (0)	Storage is based on personally identifiable information with mandatory publication on the server site (0)	Storage is based on personally identifiable information with mandatory publication on the server site (0)	It collects personally identifiable information. (1)
Aesthetics	Exceptional. (3)	Limited features and option. (0)	Various style choices and chart types. (2)	Fairly good interface with clear and comprehensible design and functionality features. (2)	Minimalist style, few options, limited color palette, limited fonts. (0)
Save on a cloud-based platform for public sharing with or without limitations	The NDEx platform (http://ndexbio.org/#/) provides an open source framework where scientists and organizations can share, store, handle and publish knowledge of biological networks. (3)	Functionality is not fully supported. (0)	Privacy settings are not supported. An account is required by the reader in order to see a user's graph. (1)	No privacy settings. Storage is done via the user's account with a limit of 1000 views for 1 user in the free version. (1)	No time or space constraints are specified. (2)

SOLUTIONS AND RECCOMENDATIONS

The presented method for evaluating data journalism systems can be used as a quick evaluation method to be used improvements should be proposed in order to achieve the ultimate goal, which is a well-established objective method for such software. A basic limitation of the method is that in its current form it is applied by a single author, which makes it a subjective opinion in some cases.

Table 3. Comparative evaluation of apps: Gephi (0.9.2)/Infogram/Plot. Ly/Tableau Public (10.5)

Evaluation Feature	6. Gephi (0.9.2)	7. Infogram	8. Plot.ly	9. Tableau public (10.5)
Ability to handle	The user has complete control during the processing of the graph (3)	There are restrictions on options that are removed only if paid. (storage options, logo removal, more types of maps, etc.) (2)	Many graph formatting capabilities are supported through the following tabs: general, traces, axes, legend, colorbars, annotation, shapes, images, themes, built in. (3)	The user has full control over the final output format of his/her work with a satisfactory format menu of the imaging features through tabs easily managed by the average user. (3)
Support material	Knowledge base is provided (wiki), forums/facebook group (with registration) & online documentation. (3)	Chat, search engine, tutorial, videos, FAQ are supported. (3)	There are detailed instructions for using the application and community support.. (2)	A wide range of support material is supported (tutorials, webinars, chatting, demos, etc.). (3)
Ease of use	The menu is easy to read and functional without demanding extensive knowledge. (3)	User-friendly interface quite intuitive. (3)	Some menu features require more specific knowledge. (analysis, grouping and aggregation functions). (2)	Very good GUI, friendly to the average user, with the ability to instantly track the changes made. (3)
Learning time	It requires time > 5 hrs for a beginner to familiarize themselves with the features and capabilities of the software. (0)	It requires time < 1 hr for a novice user to become familiar with the application's functionality. (2)	It requires moderate time. (1 hr - 5 hrs). (1)	It requires time > 5 hrs for a novice user to become familiar with its functionality, which offers a lot of experimentation opportunities. (0)
Making use of previous knowledge	Previous experience with similar graph creation software reduces learning time. (1)	The novice user can be helped with the previous experience of similar platforms. (2)	Previous experience with other software or previous versions is recommended. Quite intuitive. (1)	A previous experience on similar platforms works positively as it potentially accelerates the learning process (1)
Processing power	The processing of the graph captures memory on the user's PC, so the performance depends on the RAM and the system's graphics card characteristics. (3)	At the 5 MB limit the platform does not respond. (0)	We successfully uploaded files up to 20 MB. (1)	We tried to upload a 900,000 line file (30MB) (with line limitation for excel 2010 at 1,048,576 lines) without success. (2)
Login requirements	No login is required at any stage of network processing and storage. (3)	An account is required to use the platform. (0)	Login is required for all chart studio functions in the community plan. (0)	Editing and formatting do not require login while storage and publishing require a connection to the server. (2)
File Type Requirements (Input)	It accepts files of many and different types except .ods spreadsheets. (2)	It accepts xls,xlsx, csv, json, upload from google drive & dropbox.. (2)	It accepts csv & excel files. (0)	Formats such as xls, xlsx, csv, tab, txt, json, kml, shp, sav, R files and pdf are supported. (2)
Cost for "full" version	Free. (3)	\$228/year for the pro version. (0)	\$840/year for the pro version. (0)	Free in public edition. (3)
Built-in analytics	A complete set of metric statistical analysis of the network is available: Average Clustering Coefficient/Average Path Length/Betweenness Centrality/Closeness Centrality/Connected Components/Degree/Degree Power Law/Diameter/Eigenvector Centrality/Graph Density/HITS/Modularity/PageRank. (3)	Not supported. (0)	Many functions available such as curve fitting with choices of basic & advanced & moving average. (2)	A satisfactory set of statistical analysis is contained for all basic functions. (3)
Output	Many unlimited formats of output. (3)	Not supported. (0)	Supported export in several formats such as: Image: png, jpeg / Data: csv, xls, json, ppt / Code: R, MATLAB, Julia, plot.js, node.js / HTML: html, Zip archive, Embed URL. (3)	It is possible to output the table in csv and / or the workbook with the data (twbx format). Also visualization can be downloaded by the user in pdf, png format. (1)

Table 3. Continued

Evaluation Feature	6. Gephi (0.9.2)	7. Infogram	8. Plot.ly	9. Tableau public (10.5)
Data collection	It maintains little or no information.. (3)	It gathers and maintains all information that has been uploaded, allows third-party access to information. (0)	It collects personally identifiable information and allows third-party access to visualizations in the community plan we evaluated. (0)	Storage is based on personally identifiable information while third party access is allowed in visualizations. (0)
Aesthetics	Many features of graph display (development algorithms) and tag and font formatting (3)	Various style choices and chart types. (2)	Many style options available, such as color, font, chart type, etc. (3)	Many style options available, such as color, font, chart type, etc. (3)
Save on a cloud-based platform for public sharing with or without limitations	There is no such possibility. (0)	Storage limit for testing is 10 projects. Privacy settings are also not supported. (1)	The community plan we evaluated offers storage space up to 25 charts without the possibility of privacy settings. (1)	The storage is done through the user's Tableau account with privacy setting capabilities. (on the user's account, it is possible to switch the display to others when viewing the user's profile or search). (3)

Table 4. Overall comparative rating

No	Feature	Tableau	Data wrapper	Datavisual	Infogram	Plot.ly	Filtergraph	Gephi	Cytoscape	Datacoplia	Category

Comparing to the work of Atwood & Reznik-Zellen (2018), our study showed (in terms of common criteria) that although there are many subjective characteristics, the overall scores were relatively close together. The method could gain more from some improvement. Some points we can suggest are:

Table 5. Differences in both application evaluations

1. Stricter refinement of the criteria to minimize the strongly subjective nature of some such as:
 - i. Learning time that is related to the user’s cognitive and empirical level. It can be more accurately assessed if a target is set where the user-evaluator is required to achieve a visualization of specific standards based on specific data that will be given to them. Evaluation scale times may be revised because they are related to the target.
 - ii. The use of prior knowledge: this criterion should also be referred to in relation to the novice user (more in relation to their empirical level of similar applications). The user-evaluator should evaluate the criterion based on whether experience in similar applications would speed up the learning process.
 - iii. Ease of use with a novice user again and provided the necessary minimum time to familiarize with the application should not exceed 1-2 hrs.
2. The criterion “cost for full version ” must determine whether the prices are for individual, student or professional use since the prices in many of them have a big difference.
3. Additional independent comparative evaluations in order to evaluate and improve existing criteria and to possibly supplement them with new ones.
4. It should be examined whether the above methodology can be applied with credible results in other technological fields of data journalism such as applications aimed at collecting and filtering data (e.g. OpenRefine, Nomenclature), scraping technologies (e.g. Artoo.js, Elex, Zup) publishing (e.g. Listify, Tarbell) etc.

FUTURE RESEARCH DIRECTIONS

Data journalism is an umbrella term that encompasses an ever-growing set of tools, techniques and approaches to storytelling. It can include everything from traditional computer-assisted reporting to the most cutting-edge data visualization and news applications. As such, data journalism tools and technologies should be tested and evaluated more formally and by more experts in several fields, especially their final users: journalists. Moreover, future research should be directed towards three axes:

- evaluation of other components / functions of data journalism tools (apart from the visual imaging component)
- inclusion of more systems in future evaluations (without applying exclusion criteria as those described in this chapter)
- refinement of current tools and technologies, driven by formal evaluations and journalists' needs.

The goal of future research should be the establishment of a framework for qualitative assessment of data journalism applications, as well as widely accepted standards for evaluating data journalism tools.

CONCLUSION

The technologies that support this powerful and highly interesting stream of data journalism are in a phase of intense productivity. Technology users have many options to best support a story without using specialized knowledge. On the other hand, there is a lack of methodological evaluation criteria from the user's point of view in order to help those interested in finding the application that best meets their needs.

We performed a comparative evaluation of nine applications covering the thematic fields of graphs and interactive charts based on a methodological approach on the basis of 14 usability and functionality criteria. The evaluation conducted showed that desktop applications show higher scores due to more and more powerful features. The other web-based applications generally exhibit lower levels of usability and functionality features as it has been described in detail.

As a general conclusion, it is a fact that literature shows a lack of studies and methodological tools for evaluating the technologies used by data journalism, which include several different types of applications. Research should therefore continue in the direction of standardizing a commonly accepted framework for evaluating the various aspects of systems supporting data journalism (data, processing stages, methods and applications).

KEY TERMS AND DEFINITIONS

Data Journalism: Journalism based on structured data in order to support a story that makes sense to the public.

Functionality: A system evaluation criterion aimed at identifying certain functional characteristics.

Interactive Chart: A chart on which a user can achieve a certain degree of interaction in order to reshape it, for example, hover a point, zoom, play with axis, add a button, etc. It allows the reader to go deeper in its understanding of the data, since he can customize it and try to answer his own question.

Rubric: A set of evaluation criteria that are valued based on a rating scale.

Storytelling: The social and cultural activity of sharing stories, with great application to journalism.

Usability: A criterion for the evaluation of the system aimed at identifying usability features from a user's point of view.

Visualization: The visual representation of journalistic story that aims to convey the information to the reader in the best possible way.

From the Data to the Statistical Analysis of Football: The Case of the Italian Serie A League

Alessio Drivet

Geogebra Institute of Turin, Italy

INTRODUCTION

This article deals with Data Analysis and Statistics applied to football. There are many publications dealing with this topic, but here the attempt is to explain how it can be attractive for secondary school students to learn notions of statistics from the analysis of data concerning the most popular of sports. In this case the analysis focuses on the last years of the Italian Serie A League.

BACKGROUND

The statistical analysis of Big Data is probably the most advanced frontier of sport and, more recently, of football. This is true even if we must remember that analyses on the dynamics of football have been present for many years (Grehaigine, 1997; Bouthier & David, 1997), and we cannot forget that this sport has found writers who, as fans and / or sportsmen, have revived, through their writings, the charm of this game (Hornby, 1992; Soriano, 1998).

We can basically identify two components that collect data:

1. sports clubs, through a network of observatories and the use of video and computer technologies;
2. specialized companies such as Opta, Prozone, StatDNA, Wyscout, etc., which, having created large databases, can provide services against payment.

These data serve as a basis for coaches to define modules and tactics and for technical managers to guide market choices.

As declared by Davide Nicola (Corriere della Sera of 1 April 2018, page 48), one of the Italian football coaches most involved in this approach: “Everything, or almost everything, is traceable to numbers, the analysis of big data allows you to discover links between the phenomena that happen during a match and therefore to predict the future ones”.

Finally, there is a further component made up of researchers studying the phenomenon and authors of books revealing the most relevant facts to the public. The fact that the soil is fertile is demonstrated by the large number of participants in events such as the Sports Analytics Conference in Boston or, as far as Italy is concerned, the Hackaton in Trento. The winning project of this Hackathon, organized by the FIGC (Italian Football Federation) on “match analysis” mixes “subjective” elements, for example the votes given by journalists, to numbers taken from statistical sources.

DOI: 10.4018/978-1-7998-3473-1.ch051

An approach based essentially on the analysis of objective data is, for example, the one known as the POGBA algorithm (Prediction of Goals by Assessing Phases) in which the available spatio-temporal data are used to evaluate the probability that a specific game situation will lead to an attempt of realization, and therefore to estimate the probability that the same attempt will lead to the expected goal (Decroos, Dzyuba, Van Haaren & Davis, 2017).

To conclude, we would like to mention an interesting point that is based on studies on artificial intelligence and neural networks; with this approach, we can segment game into sequences of situations that are discovered in an unsupervised way and we can learn *conceptors* (a mechanism of neurodynamical pattern learning and representation) that are useful for the prediction of the future of the match (Michael, Obst, Schmidberger & Stolzenburg, 2017)

The problem is that all this is reserved for a group of specialists (Hendriks, 2016) while it would be interesting to be able to transfer part of these resources to an audience of students having two objectives:

1. explain how and where information can be found;
2. provide a concrete view of some statistical concepts and probabilities.

Since the aim is to deal with a level of information specific for the high school students, it will be used a type of statistics relatively simple: percentages, averages, probability distributions, regression and correlation.

For the first two concepts there is not much to say as they are part of a knowledge already present at previous levels of school.

As far as probability distributions are concerned, we shall limit ourselves to a simple reference.

The probability distribution is a model that associates a probability to each observable mode of a random variable.

We can distinguish two types of random variables, discrete or continuous: the probability distribution is discrete when the phenomenon is observable with an integer number of modes, and continuous when the random variable assumes a continuous set of values.

The text compares the discrete goal distribution with the Poisson distribution, used to calculate the probability $P(x)$ of success of a repeated event n times in an experiment in a given unit of time. Indicating with $\lambda = np$ the average of the successes results:

$$P(x) = \lambda^x \frac{e^{-\lambda}}{x!}$$

The last two terms require, from an educational point of view, a clear distinction between function (already known) and regression. The first one indicates a precise relationship between the variables while the second one, used for economic, social, biological, studies etc., describes a phenomenon, except for a certain amount of variability that is not explained by the equation. This equation defines the curve that best approximates the data; it is called the regression curve of Y on X because the dependent variable is estimated by means of the independent one. Finally, it is possible to interpret the correlation from the point of view of regression using the coefficient of determination R^2 . This coefficient represents the proportion of the variation explained by the independent variable. The square root of this value coincides with the linear correlation coefficient.

FOCUS OF THE ARTICLE

The Sources

As previously mentioned there are many sources with a huge amount of data, the problem is that, being these paid for, it is not possible to use companies specialized in teaching. In addition to this, it is not certain that the overabundance of data is necessary at a school level.

Relatively few sources are sufficient for the stated needs. The data used for this research are indicated in the Sitography.

The Tools

Regarding tools, it is possible to limit oneself to the use of a spreadsheet, exploiting its mathematical and statistical functions and the possibility to easily construct graphs.

On the Internet it is possible to find spreadsheets programmed as BetGPS (BetGPS, Directory of Betting Resources Retrieved from <https://betgps.com/blog/betting-data.php>) that interact with the data of different leagues, the compatible database can be found at the address (European Football Results, Retrieved from <http://www.football-data.co.uk/downloadm.php>). These tools can be very convenient, but in this way, you can lose the value of teaching. Building your own worksheet is more educational, and above all more fun.

Of course, more sophisticated tools could be used (Haave & Høiland, 2017; Mackay, 2017; Nair, Salian, Dave & Kadve, 2017; Pappalardo & Cintia, 2017), but this would require teaching concepts and software tools that are not familiar to the students. The possible benefits would most likely be outweighed by the time needed for learning.

The Analysis

There are several possible questions for those who want to analyze the football phenomenon and, above all, try to make reliable forecasts. For example, we can refer to this quotation: “Therefore, given the broad subjectivity of football in general, three questions can be raised: i) How can we predict the outcomes of football matches? ii) What data should we use and how should we use it? and iii) How accurate can a model to predict football game outcomes be?” (de Sousa Almeida, 2017).

For example, there are many variables that can fit into a forecast model: difference between home and away matches, results history, team composition, influence of injuries, coaching skills, etc.

In this section we will take into consideration some of these aspects, but not only, the objective is also to analyze those components, easily measurable, that can be useful for the formation of a statistical culture of the students.

1. The Advantages of Playing at Home

One of the most common considerations among football fans is the existence of the “field factor”, that is, the belief that the team playing at home is favoured mainly thanks to public incitement. What can be said about this? If you look at the years 2011-12 to 2017-18, the advantage of playing at home is obvious. However, it is noted that, except for some fluctuations, there are no significant variations (Table 1).

Table 1. Historical comparison of the 2011-17 results

Final Score	2011-12	2012-13	2013-14	2014-15	2015-16	2016-17	2017-18	Average
1	46%	47%	47%	40%	46%	48%	43%	45,3%
X	29%	25%	24%	32%	25%	21%	22%	25,4%
2	25%	28%	29%	28%	29%	31%	35%	29,3%

On the subject, numerous hypotheses (Canepa & Canova, 2016) have been made, linked to the presence of the public and its influence on the referee, or to technical, environmental or psychological issues, all credible but perhaps incomplete. Here we would like to point out an interesting approach that compares the results, once as a home team and once as a visiting team, to try to eliminate the problems related to the different strength of the teams. “The new method was presented on English Premier League, and results suggest that home team advantage is real; however, it cannot be taken for granted”. (Marek & Vávra, 2017).

2. Forecast Models

The advantage of playing at home is just one aspect to be considered. Two interesting indicators are the Euro Club Index and the Agarymathematics model.

The Euro Club Index (ECI) is a ranking of football teams that shows their respective strengths at a given time and the development of strengths over time. The ECI allows the calculation of the probability of different match outcomes (victory, draw, defeat) for future football matches.

The result of a match depends on the strength of the teams, the home advantage and the previous performance of the teams. The performance of the game will vary based on normal distribution. In this way it is possible to calculate the probability of the different results of the game.

An alternative source is, as we said, the Agarymathematics forecast model that makes predictions based on the results obtained by the teams in previous matches (Agary Mathematics, Retrieved from <http://www.agarymathematics.net/pronosticalcicio.asp>). The basic concept is the following one: as the championship goes forward, the amount of data increases. Whenever a result is added, the calculation parameters are reworked to make future evaluations more precise. The program elaborates the forecasts by considering the history of the teams examined, but also comparing the obtained results with the same teams already faced. The value that expresses the condition of the teams, and therefore the quantification of the relative strength of the contenders, is, synthetically defined by VF (Value of Form) indicated with a single number.

These two models are essentially dedicated to the prediction of the next game, but it would be interesting to see if it is possible to formulate a long-term prediction on the ground of a significant number of results. Assuming that there are situations in football where the results are driven by very simple trends (not a foregone conclusion), these trends can be grasped by basic techniques. The simplest predictive statistical technique is linear regression (Heuer & Rubner, 2014). Applying the regression to the 2014/15 Italian Football Championship the absolute difference between the real result and the forecast is sufficiently good (Jurman, 2015). The hypothesis can be easily verified by analyzing the results of the various teams, in terms of the achieved total score, and by making an estimate through the projection of the results attained in the first round. Taking into consideration the years from 2014-15 to 2017-18 and indicating with O the observed results and with S the estimated ones we obtain the following results (Table 2).

Table 2. Results of regression estimates

	2014-15	2015-16	2016-17	2017-18
$\sum O - S $	41	35	42	43
Distance	0,21	0,18	0,21	0,22

A third element that can guide us in our assessment, probably the most important, is the forecasts of those who professionally manage betting: bookmakers.

Warning: the goal of bookmakers is not to correctly predict the outcome of a game. This means that their probabilities often do not reflect a real probability distribution. Bookmakers' prices reflect their main objective: to guarantee a profit.

Let's examine a simplified version of how bookmakers set quotas. First, they collect the results of the matches of the two teams and calculate the percentages for them. They then calculate what is called the "technical picket", i.e. the probability of each of the events. This calculation is done by putting it into an equation:

- the home games played by the team;
- the difference between home games' winnings, draws and defeats;
- away matches played by the opposing team;
- the difference between the winnings, draws and defeats of away matches played by the opposing team.

In addition to the technical picket, the shape of both teams in the last 5 matches played by the two teams and the rating calculated for all matches played by the two teams in the championship (without looking at whether they are Home or Away) are also taken into consideration.

In addition to the sites of the main online betting houses, there are sites that collect the best odds. The problem is to turn these quotas into probabilities.

The odds allow you to calculate the gain related to a bet. It represents the reciprocal of the probability of occurrence of a result. A low quote corresponds to a higher chance of victory.

Note that if you turn the odds into probabilities the sum does not make 1, the difference represents the gain of the bookmaker. To obtain the correct probability, the results obtained previously should then be divided by the sum.

Example: we assume that the quotas associated with the outcome of the meeting are (Table 3).

Table 3. Example of quotas

	1	X	2
Team A – Team B	1.9	3.4	4

Table 4. Reciprocals quotas

	1	X	2	Sum
Team A – Team B	0.53	0.29	0.25	1.07

Table 5. Probability associated with possible results

	1	X	2	Sum
Team A – Team B	0.50	0.27	0.23	1.00

Let us calculate the reciprocal ones (Table 4).

The corrected probabilities will be (Table 5).

3. Probability of Victory of the Favourite Team

Suppose you've assessed with a model the probability of victory of the favorite team. What are the prospects for guessing the result of a match?

If you look at the results of the last four years of the championship of Serie A you notice that the bookmakers have progressively improved performance as they have predicted correctly 46, 54, 62 and 60 percent of results.

4. Expected Profit (Loss) From Betting on Favourite Team

Since bookmakers can be considered to provide reliable quotes (even if these change over time according on bettors' bets) based on a mixture of statistical probabilities and public opinion, a possible strategy of play could be to bet on the team considered the strongest, therefore with a lower share.

Question: If you bet 1€ on all the results with the lowest odds, for all league A matches in a year, how much can you hope to win or lose?

The answer varies from year to year, for example in the year 2014-15 there would have been a loss of 47.32 €, in 2015-16 a loss of 2.73 €, in 2016-17 a winnings of 41.89 €, in 2017-18 a winnings of 14.92 €. These data seem to contradict the predictive quality of bookmakers seen above, in reality we must take into account, economically speaking, the concept of mathematical hope. A simple example: if we bet 1 € on the favourite team that has a chance of victory of 0.45 we must expect a loss because the mathematical hope is $1 \cdot 0.45 + (-1) \cdot 0.55 = -0.1$.

5. Expected Profit (loss) by Betting on the Favourite Team Using the Odds Bias

Since betting on the favorite team does not seem an appropriate criterion, can we try to improve the strategy? One proposal (Sumpter, 2016) is to exploit the strategy known as *odds bias*. For each game the differences between the two teams' chances of winning are calculated; if the result is greater than 0.4, the favourite is the target, if less than 0.15, the draw is the target.

Does this strategy improve results? Even in this case the answer varies from year to year, for example in the year 2014-15 there would have been a gain of 4.14 €, in 2015-16 a loss of 12.61 €, in 2016-17 a loss of 6.67 €, in 2017-18a gain of 8.83€. Overall it does not seem a winning choice.

6. Goal and Distribution of Poisson

In the 2016-17 season there was an average of 2.95 goals per game. Considering the duration of a game, the probability of seeing a goal in a given minute is 0.033. Using this information, we can try to superimpose the Poisson distribution on the histogram of the goals, this is a distribution of discrete probability applicable to rare events that occur successively and independently in a given time. From Figure 1 we can see the interesting correspondence between the Poissonian model and reality (Heuer et al., 2010). A football match is a random event, but it is possible to determine a precise pattern, provided that a suitable model is used. The fact that this is not a case is because the same trend can be seen in other years.

Figure 1. Goal distribution and Poisson approximation

The Poisson model can also be used to calculate the probability of goals in a given football match. Knowing the goals scored at home and away and dividing these data by the number of matches (380) you get the coefficients of attack and defense. Then you calculate the coefficients of the two teams you want to take into account: you take the goals made and suffered at home and away and divide these values for half of the total number of games (19), in this way you get the average goals made and suffered at home and away. At this point the home team's attack value is calculated (average home goals / home goals scored) and the visiting team's defense value (average away goals / away goals conceded). Multiplying these two values by the general coefficient of home victories leads to the *Home Goal Expectancy*. Similar reasoning can be done to determine the *Away Goal Expectancy*. For example, if you take 2017-18 data

and consider the Inter-Milan derby, you'll find the values 1.83 and 1.13 that show a clear advantage for the home team. Online you can find calculation tools, such as the Poisson Distribution Calculator (Sin-ceawin, n.d.) which, given the expectation of goals of two teams, calculates the percentage probability of victory (or draw) and the likely number of goals that each team will score.

7. Relationship Between Players' Salaries and Ranking Position

Football teams are not only an organized aspect of sport, but also an economic system that moves large sums of money (Dobson & Goddard, 2001) . It is not relevant here to analyze this aspect, but only to check whether there is a relationship between the financial resources of companies and their results. This is important because the corporate objective of a football club is to maximize the number of victories (Szymanski & Del Barro, 2006).

If you look at the results of each team and compare them with the total payroll, you'll find a reasonable relationship. For the year 2016-17, the linear function $y = 0.8776x + 33.003$ is obtained with an $R^2 = 0.6399$ (Figure 2). We find similar values in other years, for example the year 2017-18 is characterized by the relation $y = 0.8747x + 32.098$ with an $R^2 = 0.7162$. We can therefore conclude that the teams that pay more, and therefore can afford top players, are favored in the race to the top places.

Figure 2. Net salaries - points

It is interesting to compare the gross amount of wages with the points earned to verify the efficiency of investments. For the year 2016-17 it appears that Juventus, winner of the championship, had a ratio of 1.57 but that at Inter (only seventh) each point cost 1.69 million euros. The best ratio was achieved by Chievo (team that refers to a district of Verona) which “paid” only 0.35 million euros every point. If 2017-18 is taken into consideration, Juventus has a ratio of 1.7 while Milan, also in seventh place, has an index of 1.8 and the palm of the team that has invested the least in relation to the points is the Crotone (the team has been relegated to the second division) with 0.3.

A particularly studied aspect is the relationship between sporting results (economists would talk about productivity) and the distribution of income within a football team. Does the equitable distribution of resources foster a better sense of group and thus improve the performance?

After collecting data on players’ salaries and the results achieved at the end of the season in terms of points, a statistical indicator capable of grasping the relationship between the two variables remains to be defined.

The choice of indicator to be used fell on the Gini index, a number between 0 and 1. The Gini coefficient is a measure used above all to measure the inequality of a wealth distribution. Low coefficient values indicate a homogeneous distribution. Most developed European countries have Gini coefficients between 0.24 and 0.36.

For Italian football teams this index is between 0.19 and 0.36 for the year 2015-16, between 0.16 and 0.26 for the following year and between 0.24 and 0.40 for the year 2017-18.

If the correlation coefficient between Gini’s index and the position in the ranking is calculated, the following values are obtained: -0.40, -0.53, 0.15.

8. Correlation Measurement

The correlation coefficient is a valuable indicator to define the strength of the relationships between goal and a series of important parameters. Let us look at some of these relationships.

A first consideration that may seem trivial, the one who scores the most and suffers the least goals wins (Anderson & Sally, 2013), but what is more impactful, prolific attacks or shielded defenses? Considering the last four championships, the correlation coefficient between scored goals and points was on average equal to 0.900, while the coefficient between conceded goals and points was -0.886. We can conclude that the winner of the championship combines both factors and that the best difference between goals made and goals conceded is an excellent indicator of balance and is sufficiently predictive of the result of the tournament.

A second question: between Corners, Penalties, Total shots, Assists, Cross, Saves, Expulsions and Offside, what is the most influential parameter in the period under consideration? The answer is Assist ($r = 0.879$) and Total shots ($r = 0.815$). For a more in-depth discussion of total shots, we can see that those who shoot more at goal are more likely to score goals ($r = 0.848$) and achieve victories ($r = 0.837$).

An interesting approach is provided by Cintia et al. (2015) of the Department of Informatics at the University of Pisa. Thanks to the availability of a large amount of data on the number of steps they have built a model that takes this factor into account. According to researchers, the team that makes more passes is more likely to win.

9. Ratio of Penalties to Balls Played in the Area

A curiosity: what was the ratio between penalty kicks and the number of balls played in the area? Looking only at the teams that have played in Serie A on a regular basis in the 2013-2016 three-year period, the ratio varies from 2 to 7 per thousand (Table 6).

Table 6. Ratio between penalties and balls played in the area

Team	Average
Torino	0,0068
Sassuolo	0,0065
Fiorentina	0,0058
Verona	0,0056
Milan	0,0054
Lazio	0,0054
Napoli	0,0051
Chievo	0,0050
Genoa	0,0049
Atalanta	0,0041
Juventus	0,0035
Udinese	0,0035
Roma	0,0034
Sampdoria	0,0025
Inter	0,0021

10. Shot Matrix Zone

Previously, we saw that it is very important to pull on goal, but it is not clear if all attempts have the same importance.

One of the most well-known studies is the Shot Position Average Model (SPAM) by Paul Riley. By analyzing the three-season shots in the Premier League, Riley has been able to determine how many shots are required to score a goal based on position: shots from outside the box, from the sides of the box and from the center of the box (Differentgame, n.d.)

This study refers to the concept of Shot Matrix Zone, a graphic representation that relates the shooting position with the possibility of scoring goals.

Applying similar principles to the Italian championship we can localize the shooting percentages from three zones: Goalkeeper's area, Penalty area, Outside area (Figure 3).

Taking into consideration the four-year period 2014-18, it is possible to compare the results (Table 7).

Figure 3. Shot Matrix Zone

Table 7. Origin of the shoots and goal

Origin of the shoots			Origin of the goal		
Goalkeeper's area	Penalty area	Outside area	Goalkeeper's area	Penalty area	Outside area
6,2%	49,5%	44,3%	21,4%	62,9%	15,7%

SOLUTIONS AND RECOMMENDATIONS

Issues

It should be considered that football is difficult to analyse using quantitative tools. Actions are not easily segmented, and scores are low, making it difficult to use statistics such as the number of assists, goal shots or goals (Ludwig & Guerrerio, 2011).

A second problem is the amount of information collected. As mentioned earlier, scholars can have access to an incredible amount of data but, in the case of scholastic research, we must limit ourselves to an analysis of a few years and therefore it is quite problematic to generalize.

As a third problem is that it would be useful to deepen the research lengthily developed in terms of algorithms by extending the exam to the available data. There are, for example, different methods of classification for pattern recognition, which can be divided into two different types: Non-Sequential Classification Methods that include machine learning algorithms that do not consider the time factor

(e.g.: Bayesian models) and Sequential Classification Methods (e.g., Markov models) that have been developed for sequential data. Of course, we are talking about models that are beyond the objectives of the text, but which could, perhaps, be mentioned.

Controversies

The research has been oriented towards the study of statistical aspects of the game, but it is also interested in bringing out some aspects of probability. Here the discussion becomes more complex because the degree of difficulty seems to be higher.

The following quotation provides interesting points for discussion: “Probability is increasingly taking part in the school’s mathematics curriculum; yet most teachers have little experience with probability and share with their students a variety of probabilistic misconceptions. Probability is difficult to teach for various reasons, including disparity between intuition and conceptual development even if it apparently regards elementary concepts. Since an education that only focuses on technical skills is unlikely to help teachers overcome their erroneous beliefs, it is important to find new ways to teach probability to them, while at the same time bridging their content knowledge and their pedagogical content knowledge” (Batanero et al., 2005).

FUTURE RESEARCH DIRECTIONS

The text deals with statistical and probability calculation issues, and a subsequent development could widen the horizon to include other fields of mathematics.

For example, one theme may be the relationship between a player’s position in relation to the opponent’s goal. In this case, you can analyze how wide the angle of shooting is and therefore which are the positions in which the attacker “sees better” the goal. In this case, elementary trigonometry is used (MatePristem, n.d.) but it is interesting to use GeoGebra software to study the angle dynamically. This development, with the necessary simplifications, could resume the study of Expected Goals according to the model of Michael Caley (Differentgame, n.d.) The expected goals (xG) measure the quality of a shot based on different variables such as the type of assists, the angle of shot and the distance to goal (Rathke, 2017).

A second interesting aspect concerns the geometrization of the football pitch. In this respect, the penalty area can be examined as a chessboard made up of squares $18' \times 18'$ (English imperial feet, so $18'$ is 5.5 metres), this dimension corresponds to the average distance travelled by a player in a second. The square is a basic unit of a chessboard in which attackers and defenders are compared and can lead us to analyze the pattern that can be developed. In geometric terms, the defensive cover measures the defensive competence area of a player during a game. The corresponding output consists of a polygon of the defensive zone covered by the player.

A third direction of research may refer to the analysis of penalty kicks (Hughes & Franks, 2015), not only from a statistical point of view, but also in terms of mathematical equations of motion (Couceiro et al., 2013); this is a very interesting aspect, which also involves the entire conduct of the match, the study of aerodynamics (Bush, 2013) can relate football, mathematics and physics.

CONCLUSION

The proposal contained in the text may constitute a work project applicable in a secondary school. Of course, at least for the Italian context, it must be considered that not all the addresses have the same mathematical background and therefore appropriate adaptations would be necessary.

Some summaries of the empirical results have been proposed in some workshops for high school classes, especially with reference to the subjective definition of probability, and in a training course for teachers.

KEY TERMS AND DEFINITIONS

Big Data: Term used to describe the set of technologies and methods of analysis of massive data. The term indicates the ability to analyze and relate a huge amount of data to discover the links between different phenomena and formulate predictions.

Correlation: We mean a relationship between two statistical variables such that for each value of the first variable corresponds with a “certain regularity” a value of the second.

Data Analysis: It is a process of collecting, transforming, and modeling data to highlight information that suggests conclusions and supports decisions.

Expected Goals: Assigns a value to the chances of a shot resulting in a goal.

GeoGebra: It is a dynamic software for learning and teaching mathematics that provides tools for the study of geometry, algebra, and analysis.

Gini Index: It is a measure of the inequality of a distribution. It is often used to measure inequality in income distribution. It is a number between 0 and 1.

Linear Regression: It is a linear approach for modelling the relationship between a scalar dependent variable y and one or more explanatory variables (independent variables).

Poissonian Process: It is a stochastic process that simulates the emergence of events that are independent of one another and that occur continuously over time.

Shot Matrix Zone: It is a subdivision of the soccer field into zones, each of which has a specific probability of obtaining a goal.

Automatic Detection of Semantic Clusters in Glossaries

INTRODUCTION

The most important principle of the Requirements Engineering is to perform all of its activities within the framework of the clients and users culture. This is the major difference between Requirements Engineering and the system analysis, since the latter models the context in which the future software system will be inserted, using computer science techniques, models and resources (Pressman, 2005; Sommerville, 2011). To plan the functionalities that a future software system will provide, in terms of the business process peculiarities, is not an easy task for the requirements engineer. As a first step, he or she must deeply understand the peculiarities of the context in which the future software system will run. There have been proposed several approaches to elicit and model such knowledge (Castro, Kolp, & Mylopoulos, 2002; Van Lamsweerde, 2001). Creating a glossary (Weidenhaupt, Pohl, Jarke, & Haumer, 1998) of the vocabulary used in Universe of Discourse (UoD), at the beginning of the project, is one of them. The UoD is the context in which the software is developed. It includes sources of information and people involved with the software: users, software engineers, domain experts, etc.

The research, whose main results are presented in this chapter, was done in a process, which precisely begins with developing of the Language Extended Lexicon (LEL), which is by itself a sort of enriched glossary (Leite & Franco, 1993). The fact that language carries knowledge, cultural information and reflects the substantial and particular ways of thinking of people (Crozet & Lidedicont 2000; Nettle & Romaine, 2000; Salim, 2017) has allowed, along many previous studies, to accelerate and to systematize the comprehension of the context for which the system will be developed (Leite, Hadad, Doorn & Kaplan, 2000). Besides the LEL, all the remainder models needed to establish the software system requirements, are also created using natural language; this is done to improve the communication among all stakeholders.

Lately, a deep analysis of the LEL has proven that the way in which it was used, did not take full advantage of its potential. There is some sort of hidden information, not easily perceived. In the chapter “Displaying Hidden Information in Glossaries”, included in the fourth edition of the Encyclopedia of Information Science and Technology, a strategy to visualize the grouping of terms in the LEL was presented (Ridao & Doorn, 2018). Experiments performed on real world cases have shown that the clusters obtained using syntactic resources of the LEL model, coincide with information nuclei of the application domain. Such strategy was based on graphs constructed using hypertext links embedded in the LEL model. Unfortunately, graphs of a relevant quantity of LELs do not present clearly distinguishable clusters, even when groups of related terms exist, and they may be found by human observers, after a careful scrutiny. This is the weakness of relying only on the detection of groups of terms by means

DOI: 10.4018/978-1-7998-3473-1.ch052

of the visual perception of clusters in the graph. Coping with this weakness was the motivation of the research project whose results are reported here.

Facing Structurally Complex Disciplines By Automatic Graph Construction

Disciplines dedicated to the understanding of phenomena whose dominant aspect is their structural complexity, instead of the essential complexity of their components, have lately acquired an increasing importance (Barabasi, 2002; Dorogovtsev & Mendes, 2003). The classic visual representation of these networks is done by means of graphs. What actually happens is that when the number of nodes surpasses a moderated limit, those graphs are no longer useful to observe the relevant characteristics of the network. This limitation may be tempered by using automatic graph construction. The automatic graph construction procures to reach an optimal nodes placement. The meaning of such optimal nodes placement may be rather different, depending on the aspects of the network that are to be emphasized. Some examples are the visualization of groupings or clusters, the emphasis on edges that disconnect the graph or the identification of nodes with few connections, among others. There are many examples, where the detection of groupings provides a notorious contribution to the comprehension of the phenomenon being studied (Mo, Cao, & Wang, 2012; Sarmah, Kalita, & Bhattacharyya, 2011; Zimmermann, Ntoutsis, Siddiqui, Spiliopoulou, & Kriegl, 2012). Most evident examples of this kind of problems are the organizational networks, social networks, bibliographic references networks and interest groups among many others. Configurations of nodes and connections also occur in a great diversity of other situations. They may represent physical networks, such as electrical circuits, roadways, or organic molecules. They are also used when representing less tangible interactions as might occur in ecosystems, sociological relationships, databases, or in the control flow in a computer program (Gross & Yellen, 2003, 2006; Kamada & Kawai, 1989).

Structural Approaches in Requirement Engineering

Several activities in different Requirements Engineering processes, take advantage of the use of graphs. For example, the requirements prioritization method proposed by Duan, Laurent, Cleland-Huang and Kwiatkowski (2009), analyzes documents of the Requirements Engineering process by means of detecting clusters of requirements. In Duan proposal, the requirements are included in clusters by means of an iterative algorithm. Those clusters are object of negotiations among the stakeholders to assign priorities. Requirements inherit the priority assigned to the cluster to which they belong.

In the specific case of the process in which this project was rooted, graph depicting may be used almost everywhere. This is because natural language models allow drawing many links from one model to another; but these links very soon will become almost useless even in medium sized projects. In other words, automatic graph construction may be useful along the whole process. However, the best results have been obtained from the graphs created from the LEL. The LEL model records the vocabulary used in the application domain. It describes the words and phrases used by clients and users with a meaning specific to the application domain.

Surveying the LEL from a structural point of view, it may be immediately seen that it can be depicted using a graph, where the vertices symbolize the LEL terms and the edges represent the hypertext links among them. From this point of view, the LEL may be visualized as a sort of linguistic network with a complex structure; in such a way that besides the explicit information stored in each symbol, there is implicit information stored in the relationships among symbols. To build and to analyze the graph of

the symbols of the LEL is a sort of knowledge mining. The most basic knowledge acquirable from the LEL graph is the existence of clusters of entries, which become roots for any taxonomy of the business process. Intuitively, it may be said that if the application domain is divided into areas of interest or organization fragments, then it may be expected some coupling among the terms used in such area.

This chapter describes a strategy to build automatically the graph of any LEL, improving its visualization, combined with an automatic detection of the existing clusters of terms.

The following section analyses the LEL. Then, a section describing force directed algorithms applied to graph visualization is included. After that, an automatic detection of clusters in the graph is proposed. Finally, some results, future work and conclusions are presented.

BACKGROUND

As mentioned, this research was inserted in a Requirements Engineering process fully based on the use of natural language models. The LEL drives the construction of a set of Current Scenarios (CS) devoted to describe the existing business process (Leite et al., 2000). Combining this set of scenarios, with the objective of the future software system, will lead to the creation of a new set of scenarios, called Future Scenarios (FS). These scenarios act as a proposal about how requirements engineers think about the behavior of the future business process. The validation with clients and users of these scenarios will become the ground for the specifications of the final set of software system services or Software Requirements Specifications (SRS). Current Scenarios tell to anybody of the developing team how things are now. Future Scenarios tell all stakeholders how things will be. Clients and users may not fully understand some of the terms used to describe the services of the software. The LEL of the requirements (LELr), is an auxiliary glossary to help clients and users in relation to this.

This process is biased to improve the quality of the Requirements by discussing all issues in a natural context for the clients and users. Such improvement requires additional efforts of the developing team, during the comprehension of the business process and later during the software design phase.

LEL and LELr terms are cross-linked since the description of each entry contains references to other symbols used in its definition. CS and FS contain internal links highlighting hierarchical relationships and external links pointing to the terms pertaining to the LEL or LELr. Finally, Requirements themselves have references to the LELr when mentioning one term included in it.

LEL: Language Extended Lexicon

The LEL main goal is to register symbols (words or phrases) which are peculiar to the application domain. Each entry in the lexicon is identified by a name or names (case of synonyms) and has two types of descriptions, as opposed to the usual dictionary, which provides only one. The first, called Notion, is the usual one and its goal is to describe the denotation (defines “What the symbol is”) of the word or the phrase. The second, called Behavioral Response, is intended to describe the connotation (describes, “How the symbol acts on the system”) of the word or the phrase, providing extra information about the context at hand. Entries are classified in four types, according to its general use in the UofD. These types are Subject, Object, Verb and State. Table 1 presents the Language Extended Lexicon Model.

While describing the symbols, two principles should be followed: the *principle of circularity* that intends to maximize the use of other symbols in the description of each symbol and the *principle of minimal vocabulary* that intends to minimize the use of symbols that are external to the lexicon. These

Table 1. The Language Extended Lexicon Model

LEL: representation of the symbols in the application domain language.
Syntax: $\{\text{Symbol}\}_1^N$
Symbol: entry of the lexicon that has a special meaning in the application domain.
Syntax: $\{\text{Name}\}_1^N + \{\text{Notion}\}_1^N + \{\text{Behavioral Response}\}_1^N$
Name: identification of the symbol. More than one represents synonyms.
Syntax: Word Phrase
Notion: denotation of the symbol.
Syntax: Sentence
Behavioral Response: connotation of the symbol.
Syntax: Sentence

external symbols must belong to a small subset of a natural language dictionary. These rules stress the description of the vocabulary as a self-contained and highly connected hypertext (Leite & Franco, 1993).

Automatic Graph Construction

Formally, a graph is an ordered pair of a set V of vertices and a set E of edges, in which an edge joins a pair of vertices. Normally, graphs are depicted with their vertices as points, circles or other simple geometric form, in a plane and their edges as straight or curve segments connecting them. There are different styles of representation, suited to different types of graphs or different purposes of presentation. When drawing graphs, some generally accepted aesthetic criteria are used (Fruchterman & Reingold, 1991):

- Distribute the vertices evenly in the frame.
- Minimize edge crossings.
- Make edge lengths uniform.
- Reflect inherent symmetry.
- Conform to the frame.

Unfortunately, these types of criteria do not contribute to the objective of visualizing the underlying structure of the object of study. Notoriously, effective graphs may be obtained using automatic Graph Drawing methods. Graph Drawing is an area of mathematics and computer science that combines methods from geometric graph theory and information visualization to derive two-dimensional depictions (Di Battista, Eades, Tamassia, & Tollis, 1999; Kaufmann & Wagner, 2003).

There are many techniques to draw graphs. Most of them are devoted to a specific type of graph such as trees, directed graphs and others. A family of techniques to visualize unspecific graphs is known as *force-directed*. Also known as *spring embedders*, such algorithms define the layout of a graph using only information contained within the structure of the graph itself, rather than relying on domain-specific

knowledge. Graphs drawn with these algorithms tend to be aesthetically pleasing, exhibit symmetries, and usually produce crossing-free layouts for planar graphs (Kobourov, 2013). These methods are flexible, easy to implement and provide excellent results (Walshaw, 2003). This sort of methods is based on physics analogies. Their main characteristics are:

- They model the graph as a physical system.
- The graph is obtained by equilibrating the system.

These characteristics define the two main components of the force-directed methods:

- A mechanical model of the graph representing the elements of the graph (vertices and edges), perhaps adding some aesthetical restrictions.
- An algorithm to find the equilibrium of the mechanical system.

Nodes are placed in an arbitrary initial disposition, and the forces move them to its final equilibrium location. The spring layout method of Eades (1984) and the algorithm of Fruchterman and Reingold (1991) both rely on spring forces, similar to those in mechanical laws. In these methods, there are repulsive forces between all nodes, but also attractive forces between connected nodes. Actually, these repulsive forces come from atomic models where nucleons have strong repulsive forces, which prevent the collapse of the nucleus. In both algorithms, only directly connected nodes attract themselves, while all nodes have repulsive forces.

Eades Formulae

The forces used by Eades algorithm are:

$$f_a(d) = c_1 * \log\left(\frac{d}{c_2}\right) \quad (1)$$

$$f_r(d) = c_3 / \sqrt{d} \quad (2)$$

Where f_a denotes the attraction force and f_r the repulsive force; d represents the distance among nodes. The constants c_1 , c_2 and c_3 should be experimentally adjusted to get a good visualization of the graph. The aim of the Eades algorithm is to place graph nodes in such a way that all the edges result in about the same length.

The repulsive force decrease continuously with the distance. The attraction force actually acts attracting two adjacent nodes when the distance between them is greater than an equilibrium distance d_e . For shorter distances, it becomes repulsive. The equilibrium distance is:

$$d_e = c_2$$

Fruchterman and Reingold Formulae

Having in mind the objective of making the length of the edges linking adjacent nodes shorter than the distance of the non-adjacent nodes, Fruchterman and Reingold proposed new formulae, for attractive and repulsive forces:

$$f_a(d) = \frac{d^2}{k}$$
$$f_r(d) = \frac{k^2}{d}$$

and

$$k = C * \sqrt{\frac{Area}{Number\ of\ Nodes}}$$

In this case, attractive forces are always attractive and repulsive forces are always repulsive. An isolated pair of linked nodes will reach to an equilibrium at:

$$d = k.$$

Both sets of formulae have similar behavior when d is near to zero, but they notably differ when d adopts greater values. Attractive forces are dominant for large values of d , being much stronger for Fruchterman and Reingold formulae.

To keep the graph within a given frame, the Fruchterman and Reingold method offer several options such as stopping on the border or the use of elastic or inelastic collisions or a line of unmovable artificial nodes on the perimeter of the frame with no attractive forces. In this way, the frame is defined by four walls that enclose the graph within them.

LEL GRAPH CONSTRUCTION USING FORCE-DIRECTED METHODS

Considering the explicit objective of Fruchterman and Reingold method, their formulae was the first choice to create a graph to help the visualization of clusters in LEL model. Some changes were soon introduced. In first place, the frame was removed, since dealing with connected graphs ensures that nodes will not run away. Then, framing the graph is just a matter of scaling. This change has an important additional advantage: there is not spurious alteration of the position of nodes due to wall influence or due to reaching the border.

An additional precaution was taken: to minimize the risk of lack of hill climbing, each graph was created many times departing from different initial configurations. The observed result was that for each case studied, the final graphs were always notoriously similar. Hill climbing is the need of overcoming a bad configuration by moving through a yet worse configuration before reaching a better one.

Applying this method to some glossaries chosen from a repository containing LELs of actual organizations, it reveals that a substantial number of graphs did show some degree of clustering, but in many

of them, the possible clusters were hard to distinguish or they had no clustering at all. Figures 1a and 1b depicts this sort of results. Case 1 deals with the management of agrarian production contracts, while case 2 is related with the administration of a specialized library.

Applying the Eades method to the same set of cases, also with no framing wall, it becomes evident that quality of the node placement was better. The same precaution of using several different initial configurations was taken. Figures 1c and 1d presents the graphs obtained for the same cases of Figures 1a and 1b.

Figure 1. Graph of two different LELs using Fruchterman & Reingold, Eades and modified Eades methods

All clusters seen in the graphs created with both methods were carefully checked to confirm or reject they represent information clusters in the glossary. Every single verification was positive in the sense that every pair of nearby nodes represented terms of the LEL semantically related and that every pair of faraway terms represented loosely coupled ones.

Neither Eades nor Fruchterman and Reingold methods reach their objectives. Graphs obtained with Eades formulae do not have similar length in their edges, and Fruchterman and Reingold formulae fail to put close linked nodes.

The fact that Eades method produce a better node placement does not mean that the graphs corresponding to all glossaries clearly show the existing information clusters. By the contrary, the improvement in the cluster visualization fails in a still important number of cases.

Considering that the behavior of both methods is similar for smaller values of d and rather different for larger values of d , it becomes reasonable the hypothesis that emphasizing Eades behavior may lead to even better nodes placements. This supposition leads to the repulsive force formula:

$$f_r(d) = d^\alpha$$

Where α is between -0.5 and 0. This allows a f_r force slightly different from the one obtained using square root. The rational of this new formula was to obtain a weaker evolution of f_r with the distance.

As soon as this formula was applied, it was evident that clusters became notoriously clearer. In cases where previous graph contained clusters with diffuse limits, the same cluster appeared neatly defined. For some other cases where no cluster visualization were possible, they appeared. Some other details such as the relationships among clusters or internal groups were also observable.

Best results was obtained for values of α in the range of -0.2 to -0.1. Figure 1e and 1f show the graphs obtained with the new formula for the same glossaries of Figures 1a-c and 1b-d.

One more time, the evaluation of the improvements obtained with this step shows that it is a better method to visualize clusters in graphs and the existence of a smaller set of reluctant cases where clusters remain invisible. Figure 3a shows the graph obtained for one of those cases.

It seems that no relevant enhancement could be obtained by means of changes in the node placement algorithms, at least in the domain of planar graphs. However, there is a new viewpoint in this subject: not just automatize the node placement but also automatically detect the clusters themselves.

AUTOMATIC CLUSTER DETECTION

There are several notions of clusters, most of them derived from the method used for their detection. Some of them are based on the existence of a centripetal attraction (Berkhin, 2006), where the members of the cluster are located around a central or archetypical element, existent or not. Other type of clusters is characterized by the existence of several neighbors, also members of the cluster, having similar properties (Kriegel, Kröger, Sander, & Zimek, 2011). Obviously, the first type of clusters shows a quasi-circular shape and the second one may show an irregular shape.

A preliminary observation of the graphs where the modified Eades method failed to improve the visualization of clusters, led to suppose that this is due to the presence of irregular clusters.

The phrase *similar properties* is key in the activity of cluster detection. The nodes the mechanism used for comparison and for the ponderation of the differences are centrals to find clusters carrying meaning for the phenomena under study (Everitt, 2011). In this sense, it is known the wide use of the Euclidian

distance and the risk of its use when non-commensurable dimensions are combined. It may be thought that this is not the case, since the dimensions in graphs are geometrical distances. However, it should be taken into account that building a graph consist in the representation of an object of study, with an unknown number of dimensions in a two-dimensional visualization. This may be an oversimplification.

The simplest way for detecting irregular clusters is based on the search of nodes with more than a given quantity of neighbors located at a distance inferior of a threshold (Ester, Kriegel, Sander, & Xu, 1996). This approach has two parameters:

ϵ : maximum distance allowed to be considered a neighbor

k: minimum number of neighbors

The value of k should be compatible with the number of nodes in the graph. For graphs with less than 100 or 150 nodes, the value of k should be small, even $k = 2$. In all the LEL graphs studied, the value of $k = 2$ was chosen. Once the clusters are detected, they show greater values of k and just a few cases with the value $k = 3$. The value of ϵ require a more detailed analysis. For example, in the nodes placement of Figure 2, if ϵ is greater than the distance between nodes 5 and 20, the result is that there exists just one cluster. However, if ϵ is smaller than the distance between nodes 5 and 20 and greater than the distance between nodes 3 and 27, the result is that the number of clusters is 2. Smaller values of ϵ will lead to 3, 4 or even more clusters.

Figure 2. Relationship between ϵ and the number of clusters detected

There is no way to choose a value for ϵ a priori. In fact, all possible values may be correct. It is a natural consequence that an automatic clustering cannot provide a semantic vision of the object of the study. However, it reduces the analysis to a few possible combinations. Watching the set of clusters obtained diminishing the value of ϵ , the relationships among them may be seen as a hierarchy of clusters.

Larger clusters, obtained with larger values of ϵ , give some sort of information, while smaller ones are sub-clusters providing different information.

There always will be a small value of ϵ that will lead to a set of one-node clusters. This situation gives no information at all. The pragmatic small value of ϵ can be only determined by semantic considerations: when the splitting of a previously evaluated cluster does not give new relevant information. Then, a continuous diminishing of ϵ from a $\epsilon_{\max}$ giving just one cluster will produce an increasing number of clusters by means of the splitting of one of the previous clusters. The information obtained reviewing each step, will allow deciding when to stop the creation of new smaller clusters.

Departing from a value of ϵ that treats the whole graph as a unique cluster, a continuous decrease of it requires defining a $\Delta\epsilon$. If $\Delta\epsilon$ is too small the number of steps will be larger than necessary and if $\Delta\epsilon$ is too large some details will be lost, in at least one step, since will appear more than a new pair of cluster instead of splitting an existing one.

Instead, a binary search will lead to a minimum set of semantic cluster evaluation. When in a given segment $[\mathcal{E}_1, \mathcal{E}_2]$ occurs that:

- the number of clusters for $\mathcal{E}_1$ is the same than the number of clusters for $\mathcal{E}_2 \rightarrow$ the segment will not provide new information
- the number of clusters for $\mathcal{E}_1$ and the number of clusters for $\mathcal{E}_2$ differs in more than one $\rightarrow$ the segment $[(\mathcal{E}_1 + \mathcal{E}_2)/2, \mathcal{E}_2]$ should be inspected immediately and the segment $[\mathcal{E}_1, (\mathcal{E}_1 + \mathcal{E}_2)/2]$ should be analyzed later
- the number of clusters for $\mathcal{E}_1$ and the number of clusters for $\mathcal{E}_2$ differs in just one $\rightarrow$ the split cluster and both sub-clusters should be semantically analyzed.

Following this procedure a sequence of set of clusters, $S_1, S_2, S_3, \dots S_n$ will be obtained. In general, S_j will be a set of j clusters. At every step, S_j will became S_{j+1} , by means of the splitting of one of the clusters of S_j . If this division brings new information about the UofD whose vocabulary is being analyzed by means of clusters in their associated graph is a purely semantic question. Then, this procedure should stop when the new sub-clusters are meaningless.

Taking into account that the number of nodes in this sort of graphs is not very large, the detection of the clusters existing for a given value of ϵ , can be easily found by using the matrix C_ϵ :

$$C_\epsilon = c_{ij} \text{ con } 1 \leq i \leq n \text{ y } 1 \leq j \leq n$$

Where (for $k=2$):

n is the number of nodes of the graph,

$c_{ij} = \text{'T'}$ if the distance among node i and node j is smaller than ϵ ,

$c_{ij} = \text{'F'}$ otherwise.

(‘T’ and ‘F’ are the logical values of true and false).

Being C_ϵ^* the sum of the $(n-1)$ powers of the matrix C_ϵ ; each row and column of C_ϵ^* , contains the list of all nodes of the cluster to which this row or column belong. This is indicated by a T in the corresponding columns or rows. In other words:

When:

C_{ij}^* = 'T' nodes i and j belong to the same cluster,

C_{ij}^* = 'F' nodes i and j belong to different clusters.

This algorithm may be applied for $k > 2$ with a light difference in the definition of c_{ij} (Ester et al., 1996).

Table 2 shows the results given by this algorithm for a third case, related with the control of stock of a complex material storehouse.

Table 2. Results obtained for third case

Step	Left segment	Right segment	ϵ_1	$\frac{(\epsilon_1 + \epsilon_2)}{2}$	ϵ_2	Clusters size
1	$[0, \epsilon_{\max}/2]$ Further division	$[\epsilon_{\max}/2, \epsilon_{\max}]$ Accepted	56	2	1	2, 54
2	$[0, \epsilon_{\max}/4]$ Further division	$[\epsilon_{\max}/4, \epsilon_{\max}/2]$ Discarded	56	2	2	---
3	$[0, \epsilon_{\max}/8]$ Further division	$[\epsilon_{\max}/8, \epsilon_{\max}/4]$ Discarded	56	2	2	---
4	$[0, \epsilon_{\max}/16]$ Further division	$[\epsilon_{\max}/16, \epsilon_{\max}/8]$ Discarded	56	2	2	---
5	$[0, \epsilon_{\max}/32]$ Further division	$[\epsilon_{\max}/32, \epsilon_{\max}/16]$ Accepted	56	3	2	2, 6, 48
6	$[0, \epsilon_{\max}/64]$ Further division	$[\epsilon_{\max}/64, \epsilon_{\max}/32]$ Accepted	56	4	3	2, 6, 3, 45
7	$[0, \epsilon_{\max}/128]$ Further division	$[\epsilon_{\max}/128, \epsilon_{\max}/64]$ Further division	56	20	4	---
8	$[\epsilon_{\max}/128, 3 \epsilon_{\max}/256]$ Accepted	$[3 \epsilon_{\max}/256, \epsilon_{\max}/64]$ Further division	20	6	4	---
9	$[3 \epsilon_{\max}/256, 7 \epsilon_{\max}/512]$ Discarded	$[7 \epsilon_{\max}/512, \epsilon_{\max}/64]$ Further division	6	6	4	---
10	$[7 \epsilon_{\max}/512, 15 \epsilon_{\max}/1024]$ Accepted	$[15 \epsilon_{\max}/1024, \epsilon_{\max}/64]$ Accepted	6	5	4	2, 6, 2, 1, 45
...	...	...	...	...	...	...

Departing from a $\epsilon_{\max}$, which allows seeing the graph as composed by just one cluster, the first division, produced at step 1, finds a cluster composed by only two nodes (cluster A), leaving a remainder of 54 nodes. This cluster is clearly visible in the Figure 3a. Step 2, 3 and 4 reduce $\epsilon_{\max}$ to 1/16 of its initial value. With these values, it is impossible to distinguish new clusters. At step 5, a new cluster composed by six nodes was detected (cluster B). This cluster is still visible in Figure 3a. A third cluster (cluster C) composed by three nodes, found during the step 6, was divided at the step 10. It should be noted that at step 7, both, left and right-segment must be divided. The algorithm chose the right segment (larger values of ϵ) since they will provide bigger clusters. Later steps found clusters D, E, F and G.

Figures 3b through 3f depict the evolution in cluster detection. To improve visualization, the scale of these figures is different from the scale of Figure 3a. Table 3 summarizes the underlying semantic that drives the clustering of the involved terms of the LEL.

Figure 3. Some results of the automatic cluster detection algorithm

Table 3. Semantic of detected clusters

Cluster	Meaning
A	Consumables purchase order management
B	Purchase order management
C	Withdrawals management
D	Material needs forecasting
E	Receptions management
F	Control of devolutions because of quality or due to not use
G	Current and historical stock control

FUTURE RESEARCH DIRECTIONS

In the near future, several improvements and extensions will be included in the current algorithm used for graph construction. They may be sorted as:

- **Improve the interaction among the activities:** the process is now mature to begin establishing feedbacks among the activities. So far, the construction of graphs gave some extra information about the LEL and the UofD itself, but not an effective improvement of the LEL has been accomplished. The abstractions perceived by inspecting the clusters may be used to review the LEL for possible detections of essential hierarchies and composition relationships among terms, perhaps leading to the capture of missing terms, genders and specializations. The number of clusters or the number of main clusters may be considered to redraw the graph not in the plane but using a larger number of dimensions.
- **Change visualization techniques:** Considering the main clusters present in the LEL, it is conceivable to set a point of view centered on one cluster and look at the rest of the graph as a constellation around it. Polar coordinates may be a good choice for that.
- **Applying the techniques to other explicit links:** such as hyperlinks from Current Scenarios to the LEL and from Future Scenarios and Software Requirements Specifications documents to the LELr.
- **Applying the techniques to traces:** even that the traces are not implemented as explicit links, they may export from their databases the information about the source of any piece of information that configured a given requirement or which system requirement takes care of a client or user demand.
- **Improve the quality of the models:** a revision of the frontier nodes may lead to the detection of missing components. In addition, a revision of nodes not belonging to any cluster may help to find not relevant or poorly described terms.
- **Extracting more information from the model:** an inspection of the nodes that link two different clusters may help the detection of critical points in the UofD.

CONCLUSION

The location of the nodes of a graph has been improved allowing an easy perception of clusters in most of cases. For those reluctant cases where groupings cannot be seen, an automatic detection of clusters technique has been developed. This technique has shown its effectiveness even in complex graphs.

The clusters are detected in an incremental fashion, in such a way that the number of clusters is increased by one, because of the splitting of a previous larger cluster. This allows an incremental refining of the semantic of the groups. In some favorable cases, the partition gives a semantically coherent small cluster and a big rest-of-the-world cluster. When it happens, the partition behaves as extracting coherent fragments out of an amorphous block of nodes.

The number of clusters is the result of the semantic granularity desired by the user.

The construction of graphs and the automatic detection of clusters within them provides an important improvement in the exploitation of the information content of the original model.

KEY TERMS AND DEFINITIONS

Application Domain: The context in which the software system will be used.

Graph Drawing Methods: An area of mathematics and computer science that combines methods from geometric graph theory and information visualization to derive two-dimensional graph depictions.

Force-Directed Algorithm: A method for calculating a graph layout. It calculates the layout using only information contained within the structure of the graph itself, rather than relying on domain-specific knowledge.

Language Extended Lexicon: A glossary composed by a set of symbols, words or phrases which are peculiar and frequently used in a given application domain. The symbols included in a LEL have a different meaning than the regular use. It contains hypertext links that interconnect symbols.

LEL Graph: A graph where the vertices are the LEL entries and the edges represent the hypertext links among entries.

Requirements Engineering: An area of the Software Engineering, which is responsible for acquiring and defining the needs of the software system.

Semantic Cluster: A group of terms in the Language Extended Lexicon, representing an area of interest in the business process.

An Improved Monkey Search Algorithm to Solve the Flexible Job Shop Scheduling Problems With Makespan Objective

Mariappan Kadarkarainadar Marichelvam

INTRODUCTION

Scheduling is a vital decision making processes in both manufacturing and service industries. The main objective of scheduling is to allocate the available limited resources to perform a group of tasks over a period of time to optimize some performance measures. The most important performance measures are minimization of makespan, flow time, tardiness, and lateness. A wide variety of scheduling problems were addressed by the researchers. Among them flexible job shop scheduling problem (FJSP) is considered in this paper due to its theoretical and practical significance. The FJSP is an extension of the classical job-shop scheduling problem (JSP). In the classical JSP, n jobs are to be processed on m machines and it is assumed that the n jobs have pre-determined sequences of operations and also each operation is performed on a predefined machine. In the FJSP, the operations are processed on the multiple capable machines. The FJSP is formed by assigning each operation to a machine out of a set of capable machines and sequencing the assigned operations on each machine to obtain a feasible schedule by considering a predefined objective function. The FJSP were proved to be non-deterministic polynomial-time hard (NP-hard) type combinatorial optimization problems (Garey et al., 1976). Hence, with the increase in problem size, the computational time would also increase. Therefore, the exact algorithms such as branch and bound, branch and cut, Lagrangian relaxation and dynamic programming cannot be used to solve the large size problem instances. To overcome this difficulty, researchers have developed many heuristics. However, heuristics are based on a specified thumb rule for a particular problem. Hence, many meta-heuristic algorithms are addressed in the literature. Monkey search algorithm (MSA) is one of the recently developed meta-heuristic algorithms. In this paper, an improved MSA (IMSA) is considered to solve the FJSP with makespan objective function. The main objective of the work is to develop an improved monkey search algorithm (IMSA) for solving the flexible job shop scheduling problems for minimizing makespan and validate the performance of the proposed IMSA using the benchmark problems addressed in the literature. The background of the proposed research work is presented in the next section.

BACKGROUND

In this section the literature review on the FJSP, monkey search algorithm and variable neighbourhood search algorithm are present.

DOI: 10.4018/978-1-7998-3473-1.ch053

FLEXIBLE JOB SHOP SCHEDULING

The FJSP was first addressed by Brucker and Schile, 1990. They developed a polynomial algorithm to solve the FJSP with two jobs. They also proposed hierarchical approaches and integrated approaches to solve the FJSP with many jobs. However, the exact algorithms could be used to solve only smaller problem instances. The real problems are larger in nature and hence they cannot be solved by the exact algorithms. A new neighbourhood structure was proposed by Dauzère-Pérès and Paulli (1997) to solve the FJSP. The TS algorithm was suggested by them for re-sequencing and rearranging the operation. Zhang and Gen (2005) proposed a multistage operation based GA to deal with the FJSP. Gao et al. (2006) presented a General Particle Swarm Optimization (GPSO) algorithm for solving FJSP. In the proposed GPSO, crossover and mutation operations in the Genetic Algorithm were incorporated to exchange the information and search randomly. In addition, the Tabu Search (TS) was also used for the local search. The performance of the proposed algorithm was demonstrated with the benchmark problems.

Fattahi et al. (2007) developed a mathematical model and heuristic procedures to solve the FJSP. Tabu search (TS) and simulated annealing (SA) are the heuristics proposed by them. They also addressed six different algorithms to solve the FJSP. They considered both integrated and hierarchical approaches in their research. Gao et al. (2008) proposed a hybrid GA and variable neighbourhood descent (HGVND) algorithm to solve the FJSP. Two local search procedures were introduced by them. The proposed algorithm was tested on 181 benchmark problems and the effectiveness of the algorithm was proved. Pezzella et al. (2008) presented a GA to solve the FJSP by developing different strategies to generate the initial population, selection and reproduction. They compared the results, with other GAs and TS algorithms.

Bagheri et al. (2010) introduced an artificial immune system (AIS) algorithm to solve the FJSP to minimize the makespan. In the AIS, Different strategies were developed to produce the initial population and selecting the individuals for reproduction. Different mutation operators were utilized for reproducing new individuals. Xing et al. (2010) addressed a knowledge-based ant colony optimization (KBACO) algorithm to solve the FJSP. In the KBACO, the knowledge model learned some available knowledge from the optimization of ACO. The existing knowledge is then applied to guide the current heuristic searching. Yazdani et al. (2010) solved the FJSP by a parallel variable neighbourhood search (PVNS) algorithm to solve the FJSP. The proposed method increased the diversification and the exploration in the search space. Al-Hinai and ElMekkawy (2011) introduced a hybrid GA (HGA) to solve the FJSP. The initial population generation algorithm and a local search method were combined in the HGA and hence the performance of the GA was improved. The proposed HGA outperformed other versions of GA.

Yuan and Xu (2013) presented two algorithms for solving the FJSP with makespan criterion. Hybrid harmony search (HHS) and large neighborhood search (LNS) are the two algorithms. In the HHS, a local search procedure was carried out to improve the solution quality. The proposed algorithms were used to obtain the new upper bounds for the benchmark instances. A teaching-learning based optimization (TLBO) algorithm was proposed by Baykasoğlu et al. (2014) to solve the job shop scheduling problems. González et al. (2015) addressed the scatter search (SS) algorithm combined with path re-linking and TS for solving the FJSP with makespan objective. They compared the performance of the proposed algorithm with several other algorithms addressed in this literature for standard benchmark problems. A biogeography based optimization (BBO) algorithm with some heuristics was proposed by Lin (2015) for solving the FJSP. He also introduced a path re-linking technique, an insertion-based local search heuristic and an efficient machine assignment rule. Cinar et al. (2016) developed a priority-based genetic algorithm (PBGA) for solving the FJSP. In the proposed algorithm, the priority of each operation was represented by a gene on the chromosome. Iterated local search (ILS) was applied to the chromosomes at

the end of each reproduction process to improve the solution quality. The computational results revealed the effectiveness of the proposed algorithm for the benchmark problems. Li and Gao (2016) suggested an effective hybrid genetic algorithm to solve the FJSP to minimize the makespan. In the proposed algorithm, the GA is hybridized with the tabu search (TS). The GA was used for exploration, and TS was used for exploitation. Six different benchmark problems were used to evaluate the performance of the proposed algorithm.

Cruz-Chávez et al. (2017) addressed a simulated annealing (SA) algorithm accelerated by a partial scheduling mechanism and a cooling schedule mechanism to solve the FJSP to minimize the makespan. The computational results demonstrated the better performance of the proposed accelerated SA (ASA) for the benchmark problem instances of different problem sizes. Marzouki et al. (2017) introduced a multi agent model based on chemical reaction optimization with greedy algorithm for solving the FJSP. Phu-ang and Thammano (2017) developed a new memetic algorithm based on marriage in honey bees optimization algorithm for solving the FJSP. Four new features were introduced to get the global optimum solutions. An improved ant colony optimization (IACO) was proposed by Wang et al. (2017) to minimize the makespan for FJSP. A real scheduling problem and two sets of well-known benchmark instances were considered to evaluate the performance of the proposed IACO.

Gaham et al. (2018) applied an effective discrete harmony search algorithm to solve the FJSP with makespan criterion. Kato et al. (2018) solved the FJSP using a hybrid particle swarm optimization and random restart hill climbing approach. The proposed algorithm introduced new strategies in the population initialization, displacement of particles, stochastic allocation of operations, and management of scenarios partially and totally flexible. Liang et al. (2018) presented an improved hybrid immune algorithm to tackle the FJSP. A hybrid encoding method was used and based on that adaptive crossover operator and mutation operator were introduced. The adaptive crossover probability and mutation probability were used in the operation of immune for the antibody population. A hybrid algorithm based on simulated annealing algorithm was introduced to avoid the local optimization. Marichelvam et al. (2018) suggested a hybrid lion optimization algorithm (HLOA) to tackle the FJSP to minimize the makespan. A constructive heuristic was used to generate an initial solution to improve the solution quality. They conducted computational experiments with the benchmark problems and proved the effectiveness of the HLOA. Marzouki et al. (2018) developed a multi-agent model based on combination of chemical reaction optimization algorithm with tabu search (TS) to solve the FJSP.

From the above literature review, it is evident that whenever a new algorithm was developed, it was also applied to solve the FJSP with different objective functions. Moreover, each proposed approach has its own merits and demerits. Further, due to the technological developments in the computing facility, the computational time is also reduced by applying the new algorithms.

MONKEY SEARCH ALGORITHM

Monkey search algorithm (MSA) is one of the important meta-heuristic algorithms developed by Zhao and Tang (2008). It is based on the simulation of mountain-climbing processes of monkeys. Kammerdiner et al. (2009) proposed the MSA to solve the multidimensional assignment problem (MAP). Tao et al. (2010) solved the gas filling station project scheduling problem using the MSA. Wang et al. (2010) applied a discrete MSA for transmission network expansion planning. Zhang et al. (2011) developed an intrusion detection technology based on the MSA to improve the performance of Intrusion Detection System. Ituarte-Villarreal et al. (2012) proposed the MSA for a hybrid microgrid to find the proper

configuration of components to minimize the total lifecycle cost and greenhouse gas emissions. Yi et al. (2012) modified the MSA to obtain the optimal sensor placement.

Jia et al. (2015) developed a triaxial accelerometer monkey algorithm (TAMA) for solving the optimal sensor placement problems of triaxial accelerometers. Lenin et al. (2015) addressed a modified MSA for solving optimal reactive power dispatch problem to reduce the power loss. The performance of the proposed algorithm was tested with the standard IEEE 30 bus test system. Peng et al. (2016) suggested a chaotic MSA to solve the optimal sensor placement problem. In the proposed algorithm, the initial solutions were generated by using chaos variable and binary coding to enhance the global search capability. Then, a greedy strategy was adopted to improve the efficiency of local search. Zhou et al. (2016) introduced an improved MSA (IMSA) to solve the 0-1 knapsack problem. In the IMSA, the cooperation process was introduced to speed up the convergence rate of the algorithm. Moreover, the greedy strategy repair process was used to correct the infeasible solutions and improve the quality of the feasible solutions. A detailed literature review on MSA was presented by Devi and Sathya, (2017). Devi and Sathya, (2017) also proposed the MSA to solve the robot path planning and vehicle routing problems.

Marichelvam et al. (2017) introduced a hybrid MSA (HMSA) to solve the flow shop scheduling problems with multiple objectives. Minimization of makespan and total flow time was the objective function. In the HMSA, the dispatching rules and constructive heuristics were incorporated with the MSA to improve the solution quality. Recently, Atta et al. (2018) proposed the MSA to solve the incapacitated facility location problem. Elmar Kuliev et al. (2018) addressed the MSA to solve the partitioning of electronic computer equipment components which is one of the most important design optimization problems. From the above literature review, it is evident that there is no reported application of the MSA to solve the FJSP. Hence, in the present work an attempt is made to solve the FJSP using an improved MSA (IMSA). In the IMSA, the variable neighbourhood search (VNS) algorithm (Mladenović and Hansen, 1997) is implemented after the monkey search algorithm to enhance the solution quality.

VARIABLE NEIGHBOURHOOD SEARCH

The Variable Neighborhood Search (VNS) is a Metaheuristic that is associated with an iterative local search algorithm. Sevkli and Aydin (2006) applied the VNS algorithm to solve the job shop scheduling problems. Zhang et al. (2008) presented a Variable Neighborhood Genetic Algorithm (VNGA) to solve the FJSP to minimize the makespan. In the VNGA, the GA was hybridized with the VNS algorithm. Amiri et al. (2010) addressed a VNS algorithm to solve the FJSP with makespan objective function. Various neighbourhood structures related to assignment and sequencing problems were used by them to generate the neighboring solutions. Benchmark problems were used to evaluate the performance of the proposed algorithm. Pongchairerks (2014) used the VNS algorithm to solve the job shop scheduling problems. Lan et al. (2016) introduced an improved version of VNS algorithm to solve the robust job shop scheduling (JSS) problem with uncertain processing times to minimize the makespan. To obtain the advantages of both the monkey search algorithm and the VNS algorithm, both are hybridized in this chapter. The FJSP definition is presented in the next section.

FLEXIBLE JOB SHOP SCHEDULING PROBLEM DEFINITION

A set of n jobs are to be processed in the shop with m machines. Each job consists of n_j operations and each operation may be processed in any one of the machines. A job may be processed in only one machine or two machines. In some cases, a job may be processed by all the machines. The objective is to determine a schedule to minimize the makespan. Makespan is defined as the maximum completion time of the jobs in the production system. Makespan minimization is an important objective function for the effective utilization of resources. Hence, makespan minimization is considered in this chapter. The mathematical model proposed by Fattahi et al. (2007) is utilized in this chapter. It is quite common to make some assumptions in the scheduling literature. The following assumptions are considered in this chapter.

- All machines are available at time zero.
- All jobs are released at time zero.
- Each machine can process only one operation at a time.
- Each operation can be processed without interruption on one of a set of available machines.
- Pre-emption is not permitted.
- Set up times are incorporated into the processing time.
- The processing times are known in advance and deterministic.
- The order of operations for each job is predefined and cannot be modified.
- All machines are available continuously.

MONKEY SEARCH ALGORITHM

Monkey search algorithm (MSA) is one of the recently developed meta-heuristic algorithms. It is based on the simulation of mountain-climbing process of monkeys. In MSA, the population size of the monkeys is first defined. Then, the position of each monkey is represented by a vector x_i . This position is generated randomly. The position of the monkeys is changed by the step by step climbing process. The climb process in the MSA was originally designed to use the idea of pseudo-gradient-based simultaneous perturbation stochastic approximation, a kind of recursive optimization algorithm. The climbing process is used to improve the value of the objective function. After the climbing process each monkey arrive its own mountain top. Then, each monkey will look for other higher points than its current position. If a higher mountain is found, the monkey would jump thereby using its eye sight. The eye sight of a monkey is defined as the maximal distance that the monkey could watch. The position is updated. Then, the new searching domains are found by the monkeys by using the current positions as a pivot. This stage is known as somersault process, and will yield a new position for the monkeys. The objective function values are evaluated. The process will be stopped if the number of iterations is satisfied. Main processes of the algorithm are given below (Zhao and Tang, 2008; Zhang et al., 2011):

Solution Representation

Define population size of monkeys (M), for any monkey $i \in \{1, 2, \dots, M\}$ defines its position $x_i = (x_{i1}, x_{i2}, \dots, x_{in})$ which expresses one solution of the optimization problem with n dimensions.

Initialization

Generate monkeys' initial solutions randomly.

Climb Process

I. Randomly generate a vector $\Delta x_i = (\Delta x_{i1}, \Delta x_{i2}, \dots, \Delta x_{in})$, where Δx_{ij} is set as a and a is called step length of the climb process.

$$\text{II. } f'_{ij}(x_i) = \frac{f(x_i + \Delta x_i) - f(x_i - \Delta x_i)}{2\Delta x_{ij}}, \quad j = 1, 2, 3, \dots, n.$$

Vector $f'_{ij}(x_i) = (f'_{i1}(x_i), f'_{i2}(x_i), \dots, f'_{in}(x_i))$ $x_i \leftarrow y$ is called the pseudo-gradient of the objective function at point x_i .

III. Set $y_j = x_{ij} + \alpha \text{sign}(f'_{ij}(x_i))$, $j = 1, 2, 3, \dots, n$ and $y = (y_1, y_2, \dots, y_n)$

IV. Let $x_i \leftarrow y$ provided that y is feasible; otherwise keep x_i .

V. Repeat steps I – IV until there is little change on the objective function in the respective iterations or the maximum allowable number of iterations N_c has reached.

Watch-Jump Process

I. Randomly generate real number y_i from $(x_{ij} - b, x_{ij} + b)$, $j = 1, 2, 3, \dots, n$. b is called the eyesight of the monkey which indicates the maximum distance that the monkey can watch.

II. Let $x_i \leftarrow y$ provided that $f(y) > f(x_i)$ and y is feasible. Otherwise, repeat step I until an appropriate point y is found or a certain number of watch times has been reached.

III. Repeat the climb process by employing y as an initial position.

Somersault Process

I. Randomly generate a real number θ from the somersault interval $[c, d]$.

II. Set $y_j = x_{ij} + \theta(p_j - x_{ij})$, where $p_j = \frac{1}{M} \sum_{i=1}^M x_{ij}$, $j = 1, 2, \dots, n$. $p = (p_1, p_2, \dots, p_n)$ is called somersault pivot and $(p_i - x_{ij})$ is the somersault direction of monkey i .

III. Set if $y = (y_1, y_2, \dots, y_n)$ is feasible. Otherwise, repeat steps I and II until a feasible solution y is found.

Termination

The above steps are repeated until the stopping criterion is met. The number of iterations is used as stopping criterion.

IMPROVED MONKEY SEARCH ALGOIRTHM (IMSA)

In order to improve the solutions, the heuristics are hybridized with the MSA. Ziaee (2014) established a heuristic algorithm to solve the FJSP with makespan objective. In the IMSA, one of the initial solutions is generated using the heuristics. The remaining solutions are generated randomly. Moreover, the VNS algorithm is used after obtaining the optimal solutions using the MSA. A set of neighbourhood structures of the optimal solution are generated by the shaking procedure. The adjacent pairwise interchange scheme and swap (or exchange) scheme are also used in the neighbourhood search. Then, a local search algorithm is used to improve the new solution. The solution is compared with the optimal solution and based on the makespan value the best solution is obtained. This process is repeated until the stopping condition is reached. Number of generation is the stopping criterion.

IMSA FOR FJSP

In the IMSA, the required parameters are defined first. One of the initial solutions is generated using the heuristics developed by Ziaee (2014). The remaining solutions are produced randomly. To obtain these random solutions, real random numbers are generated between the interval $[0, 1]$. These random numbers are considered as random positions of the monkeys. The smallest position value (SPV) rule described by Bean (1994) is used to convert the continuous position of the monkeys into the discrete job permutation. The parameters used by Zhao and Tang (2008) is considered in this chapter. The objective function values are calculated for all the monkeys. To improve the objective function values, the climbing process is carried out by changing the position of the monkeys. In this chapter, the position of the monkeys is updated by using the velocities of the monkeys (Marichelvam et al. 2017). This is vital as the monkeys attempt to go to the top most position with certain velocity. The objective function values are again estimated for these new positions. This process is repeated until the maximum climb number is reached. Then the watch jump process and somersault process are carried out. This process is repeated until the required number of iterations is completed. At the end of the above steps, the best solution is obtained. For this best solution, a fixed number of neighbourhood structures are created. Then, a new solution in the neighbourhood of the current solution is obtained using the shaking procedure. The adjacent pairwise interchange scheme and swap (or exchange) scheme are used in the neighbourhood search. A local search algorithm is applied to improve the new solution. The solution is compared with the optimal solution and based on the objective function value the best solution is obtained. This process is repeated until the stopping condition is reached. Number of generation is used as the stopping criterion in this work.

SOLUTIONS AND RECOMMENDATIONS

The proposed algorithm is coded in C++ and run on a PC with an Intel Core Duo 2.4GHz CPU, 2GB RAM, running Windows XP. The parameters of the proposed algorithm are presented in Table 1. To validate the proposed algorithm, the benchmark problems developed by Dauzère-Pérès and Paulli (1997) are used in this chapter. The benchmark problem set consists of 18 problems. The number of jobs ranges from 10 to 20, number of machines ranges from 5 to 10, number of operations for each job ranging from 15 to 25, and number of operations for all jobs ranges from 10 to 100. The results obtained by the proposed HMSA are compared with many other algorithms such as discrepancy search (DS) algorithm proposed

Table 1. Parameters of the proposed algorithm

SI. No.	Factors	Levels
1	Population size (M)	100
2	Mutation probability	0.01
3	Climb number (N)	2000
4	Eyesight (b)	0.5
5	Somersault interval [c, d]	[-1, 1]
6	Number of iterations	500

by Hmida et al. (2010), effective genetic algorithm (EGA) developed by Zhang et al. (2011), GPSO algorithm, HGA, HHS algorithm, integrated approach using tabu search (IATS) proposed by Dauzère-Pérès and Paulli, 1997, SS algorithm and TS algorithm introduced by Mastrolilli and Gambardella, 2000 addressed in the literature. The result comparison of different algorithms is presented in Table 2. From the result table 2, it is concluded that our HMSA outperforms many algorithms DS, GPSO, HGA and IATS algorithms for all the 18 problem instances. The performance of our HMSA is similar to EGA for 7 problem instances and superior to EGA for the remaining 11 problems. While comparing our HMSA with the HHS algorithm, our HMSA provides better results for 16 problem instances whereas for two problems both the algorithms provide the similar makespan values. It is evident that our algorithm is superior to the SS algorithm for 7 problems and TS algorithm for 17 problems.

The Relative Deviation Index (RDI) is also used as a performance measure to compare the performance of different algorithms. RDI is computed by using the following equation:

$$RDI = \frac{C_{\max - Algorithms} - BKS}{BKS}$$

Table 3 demonstrates the RDI comparison of different algorithms. Lower RDI values indicate the better performance of the algorithm. From the table it can be easily concluded that the performance of the proposed algorithm is better than many other algorithms. From the RDI values, the mean RDI (MRDI) is calculated. The MRDI comparison of different algorithms is shown in Table 4. The MRDI value for the proposed HMSA is 0.96 which is lower than other algorithms. From the above result comparison it can be concluded that the HMSA is superior to other algorithms to obtain the optimal solutions. The better performance of the proposed algorithm is due to the hybridization of the MSA with the VNS algorithm. However, the computational time comparison is not considered in the present work as for many algorithms the details are not available.

MANAGERIAL IMPLICATIONS

The proposed improved monkey search algorithm is very simple and effective, and it would reduce the time to obtain the optimal schedule in any scheduling environment. The present study offers a structure for practicing engineers and shop floor managers to schedule large sized problems with less computational time. Hence, this would be very much useful to improve the productivity. The inventory may

also be reduced. Finally, the total cost of the system would be reduced and the profit of the organization would be increased.

FUTURE RESEARCH DIRECTIONS

The proposed algorithm can be used to solve real industrial scheduling problems. The proposed algorithm may be used for solving the flexible job shop scheduling problems with stochastic processing times. The consideration of due date related objective functions, multi-objectives, setup time, machine break down would be some other scope of the present work. The proposed algorithm may be combined with other heuristics and meta-heuristics to enhance the solution quality.

CONCLUSION

An improved monkey search algorithm (IMSA) is presented in this chapter for solving the FJSP to minimize the makespan. The variable neighbourhood search algorithm is hybridized with the monkey search algorithm to obtain optimal or near optimal solutions. 18 benchmark problems used in the literature are considered in this chapter. The computational results reveal that the proposed algorithm is better than the hybrid genetic algorithm, enhanced genetic algorithm, simulated annealing algorithm, hybrid harmony search algorithm, scatter search and particle swarm optimization algorithms for most of the problems.

KEY TERMS AND DEFINITIONS

Makespan: Makespan is defined as the completion time of the last job to leave the system.

Monkey Search Algorithm: A recently developed meta-heuristic algorithm to solve the optimization problems.

NP-Hard Problems: Non-deterministic polynomial time hard problems.

Scheduling: Scheduling is defined as a process of allocating resources over time to perform a collection of tasks.

MDTF: A Most Dependent Transactions First Priority Assignment Heuristic

INTRODUCTION

In recent years, considering the ever-growing challenging and complex requirements of target users, several advanced real-time based applications are developed by utilizing the database framework and scheduling aspects of time-constrained databases (Shanker, Misra, & Sarje, 2006a). The transaction processing techniques were first studied from the real-time perspective in real time database system (RTDBS). The RTDBS is simply a database system which works up on real time transaction (RTT).

The RTTs are associated with deadlines. They may be categorized as soft, firm and hard based on the consequences of their deadline misses. The soft RTT's deadline miss means the result will have lesser value (positive but diminishing); the firm RTT's deadline miss means the result will have no value (zero value), and the hard RTT's deadline miss means the result may be catastrophic (negative value). Therefore, the soft/firm/ hard RTTs must be completed without missing their deadline to make sure the meeting of the objectives of executing it. This discussion makes one point very much clear that deadline computation of RTTs (priority assignment of RTTs) should be performed in a customized fashion considering the nature of the application to get the best possible outcome.

Several protocols were developed to improve overall RTDBS performance. Then, it is realized that most of the real-life problems related to the database are distributed in nature. For instance, a balance transfer transaction between users of two different banks. To incorporate all these requirements, a more advanced research area called distributed real time database system (DRTDBS) is evolved. The DRTDBS may be defined as a collection of a finite number of time-constrained distributed database systems (Pandey & Shanker, 2016) (Pandey & Shanker, 2018c) connected through a network. In DRTDBS, a distributed RTT is generated at the parent site. The coordinator of this transaction is then tasked to coordinate and perform changes at multiple sites atomically. In contrary to the traditional databases, the correctness of the result in DRTDBS based application depends on two things: logical computation performed, and the time when the result is produced & disseminated. Although the result produced is functionally right, it may lead to tragic repercussions, be unusable, or has less value if it is not produced in time (Shanker, Misra, & Sarje, 2001). To make it easy for understanding, a complete list of acronyms with their meaning is presented below in Table 1.

DOI: 10.4018/978-1-7998-3473-1.ch054

Table 1. Table of Acronyms

Acronym	Meaning
RTDBS	Real Time Database System
RTT	Real Time Transaction
DRTDBS	Distributed Real Time Database System
RTS	Real Time System
EDF	Earliest Deadline First
AED	Adaptive Earliest Deadline
AEVD	Adaptive Earliest Virtual Deadline
AAP	Adaptive Access Parameter
UD	Ultimate Deadline
ED	Effective Deadline
EQS	Equal Slack
SS	Slack-time Slice
EQF	Equal Flexibility
PSS	Proportional Slack-time Slice
NL	Number of Locks
MNL	Modified Number of Locks
MDTF	Most Dependent Transactions First

The role of priority heuristic is vital in time-constrained databases from the transaction scheduling perspective. The same can be easily understood with the help of Figure 1 which gives an abstract view of the logical transactional environment at site S.

Figure 1. Role of Priority Assignment Heuristic in RTT Scheduling

The primarily focused task in DRTDBS is to reduce transaction miss percentage. This may be done by ensuring the efficient scheduling of concurrently executing transactions (global and local). The success of transaction scheduling algorithms largely depends on the method employed to assign priorities of transactions. The concurrency control protocol and the priority assignment heuristic both have their collective and dependent responsibility of appropriately scheduling system resources mainly data items and CPU. In distributed RTT processing systems, the priority heuristic has a very close interaction with concurrency control schemes. The concurrency control protocols are widely researched topics while

very little attention has been made in designing priority heuristics. This makes it highly pertinent to thoroughly investigate existing priority heuristics which is an obvious step to further improve the system performance by coming up with an efficient priority heuristic. Though there exist few priority heuristics specifically designed for the DRTDBS in past, they mostly consider only one thing in deciding cohorts' priorities — real-time constraints of cohorts (Lee, Lam, & Kao, 1999). Still, there are many unresolved issues requiring further investigation. Thus, this book chapter first discusses the merits and demerits of existing priority assignment heuristics and then proposes a new contention-aware distributed heuristic for the priority assignment of cohorts. Here, our work specifically focuses on the following problems that are still unsolved.

1. How is 'the heuristic integrated with the concurrency control protocols' effect the system performance with reference to the problems of the data contention, cyclic restart, and deadlock (Lee, Lam, & Kao, 1999).
2. If a higher priority transaction requests to access the data item already locked by another lower priority transaction, the transaction currently holding the data item should be aborted, permitted to inherit the higher priority of lock requesting transaction or simply be blocked.

BACKGROUND

To solve the single-processor multi-program scheduling problem, two techniques were suggested in Real Time Systems (RTS) (Liu & Layland, 1973). The aim was to improve the processor utilization by assigning priorities of the tasks. This was one of the first research papers discussing the importance of deadline-based task priority assignment.

Priority Heuristics for RTDBS

The need for coming up with a priority heuristic is first felt by database researchers when they started working on the RTDBS. The simplest priority heuristic to assign priority to the transactions is by using the classic earliest deadline first (EDF) scheme. The priority is inversely proportional to the deadline. So, the highest priority is assigned to the transaction with the earliest deadline. The transaction with an earlier deadline has the advantage of accessing the data/resources first over the transactions with longer deadlines desirous to access the same data item. However, the transaction scheduled first may not necessarily be the most urgent/important one in the system. It is also found that EDF does not perform well in case of heavy load situations and leads to degradation of the system performance. This is mainly due to its nature of assigning a high priority to the transactions that are highly prone to the deadline miss. Such deadline misses lead to the wastage of the system resources, and thereby delay other concurrently executing transactions (Yu, Wu, Lin, & Son, 1994).

To overcome the above problems, an adaptive earliest deadline (AED) policy has been introduced which stabilizes the performance of EDF under overload through an adaptive admission control mechanism (Haritsa, Livny, & Carey, 1991). In AED, each incoming transaction is assigned to either HIT or MISS group and the capacity of the HIT group is adjusted dynamically through feedback. Moreover, transactions in the MISS group receive processing only if the HIT group is empty. Although AED policy provides better performance results as compared to the EDF due to its adaptive admission control mechanism, it also fails to address the fairness issue with longer transactions.

To address the fairness issue with AED, an adaptive earliest virtual deadline (AEVD) has been proposed which computes the virtual deadline of a transaction using two parameters i.e. arrival time and deadline (Pang, Livny, & Carey, 1992). The only difference between AED and AEVD is the way in which transactions in the HIT group are prioritized. The AED policy prioritizes transactions by inverting their order of deadlines. On the other hand, AEVD uses a virtual deadline in place of the absolute deadline and prioritizes transactions in the inverse order of their virtual deadlines. Here, the virtual deadline is computed in a way, so that, the longer transactions in the system can also get a fair chance to complete their execution. The simulation results confirm that the AEVD policy provides better performance as compared to AED. The AEVD policy is further extended by Dutta et al. (Datta, Mukherjee, Konana, Viguier, & Bajaj, 1996), and Adaptive Access Parameter (AAP) method has been introduced based on explicit admission control.

Priority Heuristics for DRTDBS

The above discussed EDF, AED, AEVD, and AAP schemes are developed for RTDBS based applications and they are strictly based on the assumption that the deadlines of transactions are known, and they truly reflect the urgency. Although such an assumption suits well for the RTDBS, it may not be valid with the DRTDBS. The core reason behind our intuition is that the database is distributed over more than one site in a partitioned way in the DRTDBS. A transaction may either require accessing the requisite data items from only a single site (local transaction) or from multiple sites (global transaction). Global transactions are generally longer than local transactions since executing them requires coordination between multiple sites. The execution of cohorts of a global transaction may either take place in a serial fashion or in a parallel fashion. In our study, serial execution is considered.

Although the end-to-end deadline of a global transaction can be easily determined using EDF, it may be impractical to use this policy to assign priority to cohorts since the system designer doesn't have enough information to determine individual cohort's deadline. This is mainly due to the distribution transparency (number of cohorts and their locations are not known until runtime), and the presence of triggered transactions (Xiong, Sivasankaran, Stankovic, Ramamritham, & Towsley, 1997). Furthermore, some research studies claim that assigning priorities to the cohorts equal to that of their coordinator gives poor DRTDBS performance (Kao & Garcia-Molina, 1997). Such results outline the need for designing efficient priority heuristics to assign a virtual deadline to the cohorts of a global transaction (Lee, Lam, & Kao, 1999). Some existing priority heuristics in DRTDBS assign virtual deadlines — that is computed based on the end-to-end deadline of their global transaction — to cohorts. Moreover, even if some cohort misses its virtual deadline, it doesn't directly affect the destiny of the global transaction to which it belongs. Such a cohort needs not to be restarted after its deadline miss; obviously, it may get aborted in case of data conflict. The only purpose to assign priority to the cohort is to increase the chance of successful completion of the parent transaction. The serial execution of transactions is assumed in the study done in (Lee, Lam, & Kao, 1999).

The simplest method to assign a virtual priority to the cohort is to let it inherit the priority of its parent transaction. The first policy, i.e., Ultimate Deadline (UD) (Lee, Lam, & Kao, 1999) is proposed to address the priority assignment task with cohorts using the above obvious approach. The problem with the UD is that it only considers the currently executing cohort with respect to the end-to-end deadline of some global transaction T_G however, doesn't consider the amount of time that must be given to the remaining cohorts ($T_{n+1}, \dots, T_s$) for their successful execution. To resolve the above problem, an Effective Deadline (ED) policy is proposed that doesn't add the amount of time required for the execution

of the next remaining cohorts in calculating the virtual deadline of the current cohort. The above two policies have been mathematically represented as given below.

$$\text{UD: } \text{Deadline}(T_n) = \text{Deadline}(T_G) \quad (1)$$

$$\text{ED: } \text{Deadline}(T_n) = \text{Deadline}(T_G) - \sum_{j=n+1}^s \text{Pex}(T_j) \quad (2)$$

The $\text{Pex}(T_j)$ is a predicted execution time required by cohort T_j for its execution. Both UD and ED have an intrinsic problem of allocating all the slack time (or remaining slack time, in case some of the cohorts of a global transaction has already been executed) to the currently executing cohort. As a result, subsequent sub-transactions may find that they do not have sufficient slack for their execution. In other words, these policies are biased towards the cohorts that execute earlier.

An Equal Slack (EQS) policy is proposed to address such a biased distribution of slack time within cohorts of a global transaction. It equally divides the slack time among all the cohorts of a global transaction. The EQS policy has been mathematically defined as given below.

$$\text{Equal Slack: } \text{Deadline}(T_n) = \text{ar}(T_n) + \text{Pex}(T_n) + SS \quad (3)$$

$$\text{where } SS = \frac{\text{Deadline}(T_G) - \text{ar}(T_n) - \sum_{j=n}^s \text{Pex}(T_j)}{s - n + 1} \quad (4)$$

Here, SS is a slack time slice which is equally distributed among all the 's' cohorts of a given global transaction T_G . Note that $\text{Deadline}(T_n)$ is assigned dynamically to the cohort T_n at run time, just before it is submitted for execution. The term SS is directly affected by the $\text{ar}(T_n)$ i.e. the arrival time of currently executing cohort T_n . If T_n gets restarted in the future, it will be assigned another virtual deadline which will be naturally tighter than the previous one because of a recompilation of SS using increased arrival time. The EQS heuristic is one of the widely used priority heuristics for assigning virtual deadlines to cohorts of a distributed RTTs. But, EQS severely suffers from the problems of intensive data contention, deadlock, and cyclic restart.

Equally distributing slack to all the cohorts results in the biasness towards the cohorts with comparatively smaller predicted execution time. To overcome this problem, an Equal Flexibility (EQF) priority assignment policy is proposed that distributes the slack amongst cohorts proportional to their predicted execution time. EQF has been defined mathematically as given below.

Equal Flexibility:

$$\text{Deadline}(T_n) = \text{ar}(T_n) + \text{Pex}(T_n) + PSS$$

where

$$PSS = \left(Deadline(T_G) - ar(T_n) - \sum_{j=n}^s Pex(T_j) \right) * \left(\frac{Pex(T_j)}{\sum_{j=n}^s Pex(T_j)} \right)$$

Here, PSS is a proportional slack time slice which is variably distributed among all the 's' cohorts of a given global transaction T_G based on their predicted execution time. It has been claimed that EQS and EQF improve the DRTDBS performance in terms of the number of transactions missing their deadlines as compared to UD and ED by precisely measuring the progress of cohorts. These heuristics (EQS & EQF) avoid the ill-judged delay in completing the first couple of cohorts of any global transaction that are mistakenly considering that they have larger phantom slack time; and therefore, results into a higher percentage of transactions missing their deadline.

While the above cohort virtual priority heuristics (ED, EQS & EQF) except UD, focus on assigning virtual deadline to cohorts in order to better track the progress of the global transaction, it is also equally important to efficiently handle data contention resulted in the system due to the application of such dynamic deadline assignment approaches. Although HP-2PL integrated with EQS gives considerably good performance in the DRTDBS environment, its dynamic cohort deadline assignment approach leads to the following undesirable problems.

1. Intensified data contention
2. Cyclic restarts, and
3. Deadlocks

On the contrary, data contention can be efficiently reduced using a priority heuristic based on the number of locks. The Number of Locks (NL) policy (Lee, Lam, & Kao, 1999) assigns priority of the transaction equals to the total number of locks held by all its cohorts. Although the NL policy suits well with RTDBS, it does not give better performance when applied with DRTDBS due to its inherent nature of assigning a high priority to the cohorts that arrive at a later stage of the execution of a global transaction. In simple, the NL policy is biased towards the cohorts that arrive at the later stage of distributed transaction execution and does not consider the transaction's importance in priority computation. It means that this policy favours longer transactions over shorter transactions. Moreover, NL policy is introduced for the serial execution model.

Further, a modified NL (MNL) policy (Shanker, Misra, & Sarje, 2005) is proposed for DRTDBS based applications. Here, the priority of all the cohorts associated with a global transaction may be different based on the number of locks held by them, and the priority of a cohort does not depend on the priority of any other cohort executing to complete the same global transaction. This policy is introduced for the parallel execution model, where all the cohorts of a global transaction execute in parallel to complete their data processing tasks. Therefore, it is not possible/logical to compare these two policies from a performance point of view. One simple way to handle/reduce the data contention is by using a number-of-locks based priority heuristic. The Number of Locks (NL) heuristic says that the priority of transaction is equal to the total number of locks held by it. The main reason behind the non-acceptability of NL in the DRTDBS environment is in the notion that all the locks are held by RTT in one attempt. The NL heuristic, when applied in the DRTDBS environment, assigns higher priorities to cohorts of a global transaction that arrive at a later stage of the execution. This means that the NL heuristic is biased towards the cohorts that arrive at the later stage of distributed RTT execution. Moreover, this heuristic is incapable of controlling the real data contention level as it relies purely on the number of locks held by

distributed RTT for priority computation of cohorts. In simple, this heuristic favours longer distributed RTTs over shorter distributed RTTs.

To overcome the above problems associated with the EQS and NL heuristics, the Most Dependent Transactions First (MDTF) heuristic is proposed which specifically aims at minimizing the wastages of the system resources by avoiding deadlock and cyclic restart via computing deadline of cohorts by considering data contention level; thus, minimizes DRTT miss ratio. The MDTF heuristic efficiently reduces the data contention among concurrently executing DRTTs by injecting the number of dependent DRTTs with all direct DRTTs requesting access to the conflicting data item during their priority computation.

MDTF: A Contention-Aware Priority Heuristic

The existing priority heuristics can be improved by assigning realistic virtual priorities to cohorts of a DRTT by paying special care towards the data contention problem. The Most Dependent Transactions First (MDTF) heuristic discussed below addresses the above issue.

MDTF Heuristic

The MDTF heuristic is a contention-aware priority heuristic. Each directly competing RTT has information associated with it, i.e., the size of dependent RTTs. Suppose that more than one RTTs are directly competing to access the conflicting data item. Here, the RTT with the largest number of dependent RTTs is given access to the data item. In this way, the MDTF heuristic reduces the data contention among concurrently executing RTTs.

Here, each data item has its associated linked list of waiting transaction(s). To resolve the data conflict between waiting transactions, the MDTF uses explicit information associated with the conflicting data item. Instead of using the information of the number of locks associated with a transaction, the priority is decided based on the more detailed points contributing to data contention. The transaction contributing highest in increasing the data contention level will be given the highest priority. If RTT requests to access the data item, its priority will be re-computed every time. The MDTF says that the priority of the transaction is assigned dynamically considering the number of transactions directly or indirectly waiting for the release of the locks already held by it. The informative aspects of assigning priorities to RTTs help in completing their execution with an optimal strategy of data contention control.

The MDTF heuristic reduces the data contention level by precisely analyzing whether the lock held by RTT is contributing to the data contention or not. The RTTs lock data items before accessing them. A data item held by some RTT is said to be unpopular if no other concurrently executing RTTs have requested for the grant to access it. The unpopular data item does not contribute to data contention. Moreover, if the lock held by the RTT contributes to the data contention then the next thing is to what extent it adds to the data contention. The data contention resulted due to competition to access the data item is quantitatively computed by finding out how many transactions require to access the given data item at a time in a conflicting mode. The MDTF heuristic can be mathematically defined as given below.

Priority (RTT 'T') = Number of Dependent RTTs on RTT 'T'

Moreover, in case of a tie, the priorities of conflicting RTTs are assigned using the FCFS scheme.

DISCUSSIONS

The discussions section is dedicated to the analytical study of the MDTF heuristic. Suppose that two RTTs T_1 and T_2 require to access the data item in an exclusive mode. The RTT T_1 has locked the data items d_1 and d_2 , and only d_2 has its associated linked list of four waiting RTTs. So, T_1 has four dependent RTTs. The RTT T_2 has locked the data items d_3 and d_4 both the data items have their associated linked list of one waiting transaction. It means that T_2 has two dependent RTTs. So, one can easily say that T_1 has larger number of dependent RTTs as compared to that of T_2 .

On using the NL heuristic in the above scenario, priorities of RTTs T_1 and T_2 will be two. In case of a tie situation, access of data item is granted using First Come First Serve (FCFS) policy. Such decisions may sometime result into the increased data contention level. For instance, when RTT T_2 wins the race and is granted lock to data item, allowing T_2 to execute while putting T_1 in a waiting state is not a wise decision from data contention point of view since T_1 contributes more in increasing the data contention. Thus, this heuristic does not fairly address the data contention problem.

As evident from Figure 2, RTT T_1 has 4 dependent RTTs while T_2 has only 2 dependent RTTs. Therefore, T_1 is generating larger contention in the system as compared to T_2 . According to the MDTF heuristic, the priority of T_1 is 4 and that of T_2 is 2. As a result, access to the data item may be granted to T_1 . In this way, the MDTF heuristic may better handle the data contention level in the system as compared to the NL heuristic.

Figure 2. Transaction Dependency Graph

Table 2. DRTDBS Model Parameters with their Default Values

Parameter	Meaning	Default Setting
DB_{Size}	Size of Database (No of Pages in databases)	2000 data items/site
N_{db}	No of database Sites	12
C	Number of Sub-transactions	4
AR	Transaction arrival rate per site	0-4 transactions/ sec (Uniformly Distributed)
	Communication delay among transactions	Either 1 ms or 10 ms
N_{op}	No of operations in a transaction	4-20 (Uniformly Distributed)
SF	Transaction Slack Factor	1-4 (Uniformly Distributed)
$P(w)$	Probability of write operation	0.30
	Number of disk units	1
	Number of CPU units	1
	Processing time required by CPU for accessing a data item from disk	10ms
$Local_{frac}$	Fraction of local transaction	0.60

The MDTF heuristic involves no extra message overhead in communicating the information of dependency size to the subsequent cohorts during the execution of distributed RTT; obviously, this information is sent for first-time after the execution of cohort residing at a site where distributed RTT is generated. This information is sent using a piggybacking approach. The dependency size information is piggybacked with the fork-off message and the resulting message is sent to the site where the newly generated cohort physically resides.

Performance Evaluation

Although it may be better to evaluate the performance of proposed MDTF heuristic using some practical benchmarks, there is no hands-on simulator available in DRTDBS research community or in market to assess the performance of the proposed protocol (Ulusoy, 1995) (Bestavros, Lin, & Son, 2012) (Lee, Lam, & Kao, 1999). Therefore, a DRTDBS including N number of sites was simulated in accordance with the environment assumed in earlier studies (Lee, Lam, & Hung, 2002) (Shanker, Misra, & Sarje, 2006b). An event-driven simulator is developed in C++ language. For each set of experiments, the results were calculated as an average of 10 independent runs and in each run, 20000 transactions were initiated. A mild level of resource and data contention has been ensured during performance evaluation.

DRTDBS Parameter Settings

In our experiments, each database operation is either read or write (read-then-write) operation with a probability of write operation set to 0.30. A database operation operates on a randomly chosen database page, (i.e., disk block) from the database. Default number of database pages is 2000 per site. Accessing a page from the disk requires 10 milliseconds. A range of operations from 4 to 20 are introduced that are uniformly distributed. In the default setting, it is also considered that every global transaction

Figure 3. Comparing MDTF with EQS and NL using Transaction Kill Percentage: Local Transactions

is divided into only 4 sub-transactions. The processing time required for accessing the data item from disk is assumed to be 10 milliseconds. Table 2 presents different parameters used in a simulation study with their default values.

The performance metric for the experiments performed is “Kill Percentage”, since the main goal of DRTDBS is to reduce the number of transactions missing their deadline. In case of firm real-time application, missing a deadline means that the transaction is required to be killed. Mathematical calculation of kill percentage is done as follows.

$$\text{Kill Percentage} = \left(\frac{\text{Number of transactions aborted}}{\text{Number of transactions in the system}} \right) * 100$$

Transaction arrival follows the Poisson distribution and each transaction is associated with a deadline. The Two Phase Commit (2PC) protocol is used for commit processing.

Simulation Study and Performance Results

The simulation study is performed with disk resident databases. The MDTF heuristic is compared with EQS and NL heuristics. As mentioned in Table 2, the setting represents an environment where the probability of write operation is 30%. The global transactions are in minority ($Local_{frac} = 0.60$) and are not too large ($c = 4$). Data contention is thus mild.

Figure 3 compares the MDTF heuristic with EQS and NL for local transactions using transaction kill percentage. Local transactions rarely fall under the category of lengthy transactions. The NL heuristic does not work well for local transactions since they do not lock larger number of data items during their executions. Therefore, NL heuristic is biased towards prioritizing global transactions over local ones. The NL and MDTF heuristics are purely contention-based heuristics and does not consider deadline values in priority computation of transactions. This in turn lead to the situation where the EQS policy performs better than the NL and MDTF since it considers the deadline values of local transactions for deciding their priorities. Moreover, the MDTF heuristic performs better than the NL heuristic since NL is more biased towards global transactions as compared to the MDTF heuristic.

Figure 4. Comparing CA-EQS and MDTF with EQS and NL using Transaction Kill Percentage: Global Transactions

Figure 4 compares the transaction kill percentage of the MDTF heuristic with EQS and NL for global transactions. Global transactions contribute to higher data contention as compared to local transactions because of considerably longer data item access list containing remote data items. As a result, the transaction miss rate is high for all the heuristics (NL, MDTF, and EQS). The transaction kill percentage with MDTF is higher as compared to the NL heuristic as it is exceedingly biased towards global transactions. At the same time, MDTF heuristic possesses better performance results as compared to the EQS heuristic. The proposed heuristic is a fairly balanced one with almost no biasness towards global or local transactions.

Figures 3-4 show the transaction kill percentage with different transaction arrival rates. As expected, the system misses more deadlines when the transaction arrival rate increases. This is due to the reason that a heavier workload leads to a larger number of data item access requests, longer queuing time, higher data conflict probability, higher probability of transaction blocking, and therefore, fewer transactions complete successfully (i.e., within deadline constraints). In other words, heavier workload leads to a decrease in a number of transactions that can progress concurrently without being blocked which in turn increases transactions miss percentage.

In nutshell, the proposed heuristic performs better than the EQS and NL heuristics. The performance improvements are primarily because of better assessment of contention in the system.

FUTURE RESEARCH TRENDS

Future time-constrained databases may be operative in an unpredictable environment and will need flexible run-time systems that can handle an unknown and varying number of concurrently executing transactions efficiently (Shanker, Misra, & Sarje, 2008). The point-to-point insight about future research opportunities is provided below from the DRTDBS perspective.

1. **Priority inversion:** The executing-committing conflict, during the concurrent execution of distributed RTTs, can be handled by exploiting either priority inheritance approach (Pandey & Shanker, 2017b) (Pandey & Shanker, 2018b) (Pandey & Shanker, 2018c), or lender-borrower approach (Shanker,

Agarwal, Tiwari, Goel, & Srivastava, 2010) (Shanker, Vidyareddi, & Shukla, 2012) (Pandey & Shanker, IDRC: A Distributed Real-Time Commit Protocol, 2017a) (Pandey & Shanker, 2019), or both in an integrated way (Pandey & Shanker, 2018a). These approaches have their own positive and negative aspects (Haritsa, Ramamritham, & Gupta, 2000).

2. Only a few research works have been done in the context of the handling of non-database operations; though, research in this direction may be useful to improve underlying system performance. The Non-Database Operations Aware Priority Ceiling Protocol (N-DOAP) is a recent effort in this direction (Singh, Pandey, & Shanker, 2019). In the N-DOAP protocol, the database operations are given preference over non-database operations. Consideration of the aspect of non-database operations resulted in the improvement of performance.
3. Considering the wide-spreading impact of database system based applications in recent days, researchers also started working to improve the performance of conventional databases systems by improving classic 2PC and 2PL (Gupta & Sadoghi, March, 2018) (Gupta & Sadoghi, 2019) (Pandey, Pandey, & Shanker, 2019) (Harding, Aken, Pavlo, & Stonebraker, 2016).

CONCLUSION

This book chapter studied the deadline based priority assignment heuristics in time-constrained databases and concluded that such heuristics can not significantly reduce the percentage of transactions missing their deadlines; fail miserably at high data contention. Therefore, to address the issue of data contention, the Most Dependent Transaction First (MDTF) heuristics have been suggested. The MDTF injects the size of dependent transactions of all directly competing transactions in their priority computation. It reduces the data contention by precisely analyzing the locks held by RTTs contributing to the data contention. The RTT, which contributes more to the data contention, is given higher priority so that its early completion may help in reducing the data contention level. The performance studies have shown that MDTF provides a trade-off between the NL and EQS heuristics from performance perspective due to its better handling of data contention.

Future research in the direction of advancement of existing state-of-the-art transaction priority assignment heuristics is required to come up with advanced user-oriented commercial products/services.

KEY TERMS AND DEFINITIONS

Distributed Real-Time Database System (DRTDBS): The DRTDBS consists of multiple data sites that are connected through an underlying computer network specifically used to run applications based on distributed real-time transactions.

Earliest Deadline First (EDF): As per the EDF heuristic, priority of a task is inversely proportional to its deadline. So, the highest priority is assigned to the task with the earliest deadline.

Firm Distributed Real-Time Transaction (Firm DRTT): The firm DRTT is killed in case it misses its deadline because its outcome has no value after deadline miss.

Hard Distributed Real-Time Transaction (Hard DRTT): The hard DRTT must be finished before its deadline; otherwise, it may lead to potentially catastrophic consequence.

Priority Assignment Heuristic: Act as a base for all other DRTT processing components, i.e. concurrency control and commit processing; therefore, largely affects the DRTDBS performance.

Real-Time Commit Protocols: Ensure that either all the effects of the DRTT persist or none of them irrespective of any such failure.

Soft Distributed Real-Time Transaction (Soft DRTT): The soft DRTT is not killed/aborted in case of its deadline miss because the result has some value (obviously degrading) even after the deadline miss.

Business Policy, Ethics, and Law

What Is a P2P Business Model?

Djamchid Assadi

Burgundy School of Business, France

INTRODUCTION

Since 2005, crowdfunding has disrupted the world of financing by nonconformist strategies, as carpooling, online dating, home exchanges, etc. have done in other sectors. These alternative business modes, generally called P2P for peer-to-peer, have not only disrupted the conventional sectors, but also, considering their success, have attracted at the same time new competitors. The resulting intensified competitive game has pushed these platforms to look for distinctive advantages to better position themselves in the emerging alternative modes.

Despite the growth, the concepts and models aimed at strategy and management of these P2P activities are limited. Ideas are often imported from other sectors and do not specifically include the characteristics of P2P activities. This gap leads to costs and bankruptcies. The term “business model” is one of these concepts which suffers from not having a reliable definition.

The term appeared for the first time in the ABI/Inform database in 1975 (Zott & Amit, 2009). It became a buzzword in the mid-1990s with the emergence of the e-commerce (Leiner et al., 2014). The term’s occurrence in academic work has exploded since 1995. A search in Google Scholar for research papers with “business model” in the title provides statistical evidence: respectively 1980, 1900, 1940 and 1300 since 2015.

Despite the high number of occurrences of “business model” in titles, there is still not a commonly accepted definition for it (Osterwalder & Pigneur, 2002). It is used to imply different terms such as strategy, corporate ownership of fiduciary value, stakeholder relations management, profitability and partner relationships (Ghaziani & Ventresca, 2005; Zott & Amit, 2009).

The variety of terminology used to describe business models makes the identification of an appropriate one extremely challenging in emerging sectors of P2P activities. In this paper, we conduct a literature review to build a conceptual one for P2P activities. We will then test the validity of our model with case studies research focused on crowdfunding.

BACKGROUND: REVIEW OF LITERATURE ON BUSINESS MODELS

To propose a theoretical and operational reference business model for P2P activities, the review of literature opts for a funnel approach, starting with general concepts before focusing on specific aspects.

First, we position the business model in relation to strategy because the two concepts are often mis-treated as equivalents. Second, we examine the taxonomy of business models to identify the one that corresponds to P2P activities and its theoretical foundation. Third, we look for the components of the economic model in the literature.

Strategy and Business Model

What is a business model? Etymologically, the term “model” means schematic description of the relationships between a set of entities, which can serve as an example to follow. As a result, a business model can describe the link between a company’s resources and skills to create value for both target markets and business owners.

Authors disagree on the relations between a business model and a strategy. Alike strategy, Applegate (2000) believes a business model defines a structured relationship between its different components to respond to the real world. Similarly, Magretta (2002) defines a business model as a statement about how a company operates its activities within an industry to create value. Thompson and Strickland (2001) argue that a business model is only the revenue stream and financial sustainability of a strategy

Following the above, we argue that strategy and business model are not identical, but intertwined, complementary and needed for the success of P2P platforms (Mansfield & Fourie, 2004). A strategy defines the competitive advantage for obtaining an auspicious position from rivals while a business model outlines the necessary resources, activities and processes to support and ensure that position. A strategy maps the foundation for a company’s value creation, while a business model provides arrangements to create that value.

Figure 1. A business model’s role and mission

This suggestion of strategy-business model relations is in line with what many authors who believe: a strategy states a competitive position, whereas a business model is assessed by the wealth that it creates and resources it exploits (Mansfield and Fourie, 2004; Elliot, 2002, Zott and Amit, 009). In this perspective, a business model can be considered as the link between strategy and business procedures (Mansfield and Fourie, 2004; Osterwalder and Pigneur 002, 2013). Figure 1 illustrate the links between strategy, business model and final operational activities.

Research on business models progressively explores relations with emerging topics such as extended ecosystems, digital technologies and sustainability.

For ecosystems, Hacklin et al (2018) demonstrate that business models that cope the intrinsic elements with the external environment, instead of adding new accompanying business models, positively affect value migration in (computer and telecommunications) industries. Li et al. (2018) find that busi-

ness models that leverage direct contacts in a cooperative arrangement improve their competitive position and centrality in the network. Snihur et al. (2018) study how a disruptor's gambit might dislodge powerful incumbents and shape new ecosystems through business model innovation and satisfaction of customers and partners.

Considering digital technologies, Díaz-Díaz et al. (2017) discover through a benchmarking of eight urban services in the city of Santander in Spain, that smart cities' business models that integrate the urban service of Internet of things provide positive impacts on cost reduction, energy consumption, environmental and social issues and incentivized citizens (Díaz-Díaz et al., 2017). Figueroa and Pérez (2018) consider the role of big-data within ecosystems and its impact a firm's operations, management, distributed collaboration and the valorization of collective intelligence and learning.

Sustainability is also regarded. Pedersen et al. (2018) query 492 managers within the Swedish fashion industry and find that companies with flexible business models support more efficiently corporate sustainability. Robertson (2017) argues that business model innovation can have greater long run success than product innovation because it is harder for competitors to emulate.

The Two-Sided Market as a Conceptual Basis for P2P and Crowdfunding Platforms

Once the business model is positioned with respect to the strategy, it is necessary to determine the peculiarity of online P2P business models. Tapscott et al. (2000) identify intermediation platforms for digital collaboration as a human capital extension beyond a company's conventional boundaries. Mahadevan (2000) distinguishes market-makers which link potential buyers and sellers. Assadi (2004) singles out the facilitators who accelerate, simplify and coordinates exchanges between peers. These models reinforce the major trait of online P2P platforms that neither buy nor sell, but effectively tie supply and demand by lowering transaction costs of information search, alternatives evaluation, and bargaining.

Like many researchers (Weyl, 2010; Hass et al., 2014), we postulate that the theory of two-sided markets (Rochet and Tirole 2006) constitutes the theoretical basis of the economic model of P2P platforms. The concept of two-sided market appears when two actors' demands are interdependent, i.e. the demand of one incites that of the other (Rochet and Tirole 2006). The product is useful to one party only if it is used by the other.

A credit card is only useful for consumers if it is accepted by merchants and vice versa. P2P activities which connect two sets of clients are perfect examples of two-sided markets. Applicants come on a crowdfunding platform only if there are enough contributors to meet their funding needs. Reciprocally, fund providers come only if there are enough suitable projects. Other types of this movement are auctions, "file-sharing", group buying, bartering, etc. often referred to as "Uberisation". Though we prefer the expression of "spontaneous online interactions between peers".

Yun and al. (2017) find that business models on multi-sided markets around ecosystems of platforms such as Apple App Store, Booking.com, Google Play and Hotels.com shift from focused to multiple areas, from hierarchy to networked firms, and from scope to scale economy and finally lead to regional development (as in Daegu, South Korea).

Value on two-sided markets is created by enabling direct interactions between the actors. The benefit for participants on each side of the market depends on the number of participants on the other side and the pricing decisions of the platform.

Components of a Business Model on the Internet

For Venkatraman and Henderson (1998), the three founding components of any business model are: consumer interaction, asset configuration and the knowledge leverage. For Mahadevan (2000), the value proposition for buyers, the revenue stream, and the logistics flow are. Assadi (2004) also adopts the customer value proposition and the revenue stream but considers Mahadevan's logistic as limited for building a business model and instead recommends the component of technological infrastructure. Customer value proposition, profit calculation besides resources and organizational processes are the main components for Johnson et al. (2008). The two elements, resources and processes, correspond to the concept of technological infrastructure proposed by Assadi (2004). Osterwalder and Pigneur (2002) name value for consumer segments, sustainable income streams, network of partners as components of a business model. Gassman et al. (2013) propose a triangle of questions to define the business model: "What do you offer your customers? (customer value), "How is the value proposition created?" (processes, activities and capabilities), "How is revenue created?" (income).

We believe the above-mentioned elements can be regrouped into three basic components of a business model: customer value, revenue streams and technological infrastructure. In addition to these components, some academics implicitly refer to interdependent relations between a firm and its partners and the flows of products, services, information, capital, capabilities, charges, revenues and profits among them (Timmers 1998, Afuah and Tucci 2000, Applegate 2000, Weill and Vitale 2001, Eisenmann 2002, Elliot 2002, Zott and Amit, 2003, 2009, 2010). These allusions showcase importance of ecosystems for a firm.

Figure 2. A business model's components

Figure 2 presents all the components of the model that we explain in the following.

Customer Value Proposition (CVP)

A customer value (CV) is the answer to the question "why" customers should pay for a firm's offering: because it meets their needs (Woodruff, 1997). CVs take diverse forms and depends on a consumer's perception of not only features of an offer, but also of the social and personal values it provides.

The CV a firm offer is not viewed in isolation. Consumers always compare and rank the different competitive offers to match or exceed their needs (Woodruff, 1997; Anderson & Narus, 1998; Slater & Narver, 2000; Anderson et al., 2006; Smith & Colgate, 2007, Yrjölä, 2015). Anderson et al. (2006) state

that a higher CV is not the result of all the differences from the competitors, but one or two points which give the greatest value to the customers' requirements (resonance value proposition).

Since enjoying CVs requires that customers pay not only monetary charges, but also temporal, physical, and energy dues (Christopher, 1996), we distinguish between CVP and CV. CVs are benefits such as an offering's quality, uniqueness, durability, customer service, ease of purchase, etc., regardless of monetary and non-monetary expenses a customer should pay to obtain them. While a CVP is the customer's subjective assessment between all gains and required sacrifices in return. The benefits answer to the question "Why does the consumer accept the product?" and the costs responds to "What should the consumer give to have the product?" Costs for the consumer also include opportunity costs when they miss the higher value of competitive offers.

In line with the above, we define CVP for P2P activities as the values that the two sets of customers perceive from a P2P platform's offering. This perception is a function of the overall benefits they estimate obtaining, less the sum of the pecuniary costs and non-pecuniary sacrifices they incur in return.

Revenue Streams

As every business has to ask: "For what type of value is each customer segment willing to pay?" the flow of income and the CVP have strong interactions and influence each other within a business model. A revenue streams (RS) represents a flow of earnings to individuals or organizations against CVPs they provide (Osterwalder & Pigneur 2002, Morris et al. 2005).

Assadi (2004) suggests nine sources of revenue: sales, cyberspace rental, subscription, affiliation, commission, license, databases and profiling, maintenance and market value. It places particular emphasis on the revenue-generating potential of profiling and market valuation which are often ignored in the online literature on revenue streams. Amit and Zott (2012) mention subscription fees, advertising rights, fixed transaction fees, referral fees, fixed or variable sales commissions, and margins on direct sales of goods as revenue generation methods. Fransson and Wählstrand (2018) indicate upfront payments and monthly payments as the basic revenue streams for the services that the emerging Internet of Things provides. A firm's net earning can also increase by reducing its operating costs as IBM saved \$ 350,000 in travel expenses and productivity by hosting a virtual meeting with 200 members around the world (Morrison, 2009).

An isolated source of income is often modest, so it is often necessary to combine different RSs to generate significant revenue, ensure sustainability and reduce economic risks (Eurich et al., 2011, Zheng 2015, Li 2015).

In phase with the above, we define the RS as generating regular income over a period of time for the CVP a business proposes. In this perspective, P2P platforms envision obtaining incomes from their two sets of clients. Platforms might fix a flat or zero price for one set of clients, free content for readers for example, and charge rather the other set such as advertisers (Weyl, 2010).

Infrastructural Technologies and Competencies

A business model can be considered as a heuristic scheme that unlocks the latent economic advantage of a technology to create value in accordance with the reference strategy and with partners value chains (Chesbrough and Rosenbloom, 2002). The third component of an economic model includes the resources and skills that enable a business to operate the flow of goods, information and cash to create a (unique) customer value and a sustainable competitive advantage over time (Prahalad & Hamel, 1990).

For online P2P activities, the Web 2.0 technologies and the resulting social media are the reference founding tools because they reduce transaction costs and allow users to interact spontaneously on an unprecedented scale (Surowiecki 2004; McAfee, 2006; Tapscott & Williams, 2006).

We emphasize the importance of the Web 2.0 technologies and skills as the third infrastructural component of our suggested business model for P2P activities. To our best knowledge, this is the first academic paper which highlighting the importance of Web 2.0 technologies in the emergence of P2P platforms for encouraging and facilitating horizontal transactions between peers, according to the search engine Google.Scholar.

Governance of Relationships and of Transactions Among Participating Parties

The fourth component of our suggested economic model relates to the governance of the ecosystem that affects and is affected by an organization's functioning.

Since value creation now goes beyond the dyadic “business-customer” relationship to multiple economic and social networks (Harrison and Carson 1993, Siebdrat et al., 2009, Watkins 2013, Neeley 2015), we believe the governance of these extended relations should be integrated in a firm's business model. Especially as digital technologies deploy and reduce transaction costs, firms concentrate on their core-activities and outsource the others. Sarma and Sun (2017) highlight the crucial role of the co-evolution of institutional entrepreneurs on the different stages of the (semiconductor) fabless business models. Snihur et al. (2018) show how a disruptor's innovative business model might dislodge powerful incumbents and shape new ecosystems of customers and partners. This trend is confirmed even more for P2P platforms, whose main mission is to get the most distant partners interested in direct interactions.

This extended territory of governance can legitimize a company on the market, lower its indebtedness interest rate and improve its stock valuations (OECD 2004). As a result, many oversight bodies progressively open their doors to activists for different causes such as consumer panels, environmental advocates, gender equality advocates, and workers' representatives (Hitt et al., 2012).

We posit that the extended ecosystem for online P2P activities regroups four circles of stakeholders. The first circle is internal and composed of shareholders, executive managers and employees. The second circle is that of the two sets of clients of the P2P platforms. The circle aims at partners who directly participate to the P2P platform's value chain. The forth circle is composed of government agencies, unions, communities and activists of different causes who are concerned by, however do not commercially deal with the P2P platform.

THEORY-TESTING WITH CASES

We adopt the research method of case studies to test the external validity and explanatory potential of the quadripartite paradigm we suggest against the genuine crowdfunding platforms.

The method of case study particularly satisfies our research inquiry and objectives as it supports theory building (Yin, 1981, Eisenhardt, 1989). Løkke and Sørensen (2014) affirm case studies constitute a conventional manner of testing theories since the 1970s. For more examples, one can refer to Kozinets (2002), Amit and Zott (2002) and Ashta and Assadi (2010).

The underlying principle for selecting cases within in this approach is not size, randomness nor representativeness for making inferences about the parent-population. The principle is picking a sufficient number of real cases to provide insightfulness (Eisenhardt, 1989, Patton 1990, Yin 1994). Yin (1994)

recommends one or more of the three justifications for selecting a case: critical, extreme or unusual cases. Guba (1985) and Eisenhardt (1989) endorse adding to the sample until the theoretical fullness or the experiential redundancy are reached.

In this perspective, we select 12 cases of real platforms (Table 2) originating from different countries (France, USA), dating from the beginning of the activity up to the present date, operating in different types of crowdfunding (credit, donation, equity, reward) and specialties (science, pornography, food, fashion, charity, creative industries, real estate, etc.).

Table 1. Sample of crowdfunding platforms

Credit-based	Kiva (2005, USA), Prosper (2005, USA), Babyloan (2008, France)
Donation-based	Gofundme (2009, USA), Babeldoor (2010, France)
Equity-based	Sowefund (2014, France), AngelList (2010, USA), Kiosktinvest (2014, France),
Reward-based	MyMajorCompany (2007, France), Indiegogo (2007, USA), Kickstarter (2009, USA), Ulule (2010, France)

We directly collect data from the content officially communicated on the selected platforms, and not from the interpretations or opinions, expressed in the cyberspace or else. For doing so, we explore through “back-and-forth” the platforms with an observation guide corresponding to the peculiarities of each component of our suggested pattern of business model. A good deal of data derives from the FAQ sections. However, we look also through all different pages to complete required data.

The data analysis in the approach of case studies is rather interpretive than frequencies counting (Perry et al., 1999). It relies on a constant iterative between data collection and data analysis in order to compare emerging insights with evidence from selected cases (Eisenhardt, 1989, Galunic and Eisenhardt 2000). In this process, the collected data are regrouped into categories (Miles and Huberman, 1994). In the research on hands, the categories represent the components of our suggested model: CVP, revenue streams, technological infrastructure and governance of interrelations. Within each category, we compare collected data from different platforms and induce insights.

DISCUSSION OF RESULTS

We thereafter report and discuss the content analysis of the selected platforms according to the components our theoretical quadripartite business model. All the analytic and comparative tables in this section are self-created with the data collected on different platforms as previously explained. However, their content are sometimes shortened for the sake of typographic requirements.

Customer Value Proposition on Crowdfunding Platforms

Table 3 reports the CVPs that our sample platforms declare providing for both initiators and contributors. From the common CVP of reducing transaction costs, the platforms provide more specific CVPs to each of the protagonists.

For funds seekers, the most specific CVP that online crowdfunding platforms provide is having direct access to alternative sources of funding for modest entrepreneurs (Kiva, Babyloan), individuals in financial instability and/or looking for loans at lower rate (Prosper), leaders of unconventional and

Table 2. CVPs generated by online crowdfunding platforms

	CVP for project initiator	Platform	CVP for contributors
Credit	Funding the poor's projects from all the world	Kiva	Having the possibility of truly empowering people
	Debt consolidation, easy processes, flexible payback, lower irates	Prosper	Lending from \$2,000 to \$35,000, borrowers' credit scores, searchable
	Access to loans, Empowerment	Babyloan	Supporting social causes, Select criteria
Donation	Social media coverage, small fee	Gofundme	Label of « Certified Charity »
	For social utility projects	babeldoor	Taking part in the social construction
Equity	Institutional investors support, Equity-based	Sowefund	Tax deductibility, Registered at public certifier)
	Important investments	AngellList	Equity and share for contribution
	Assistance in different categories	Kiosktoinvest	Equity-based, Tax deductibility, filtering search
Reward	Free submission, accompanying, social media, intellectual property,	MyMajorCo.	Rewards, previewing, Secured, Possibility of withdrawal
	Social media coverage, Tips and advices	Indiegogo	Supporting causes, easiness, Certified by TRUSTe
	Ownership of the project, feedbacks, Survey tools	Kickstarter	Rewards, Searchable projects through 15 categories
	Forums, social media, 7 languages and 23 currencies	ulule	Rewards, following up, filtering, 7 languages and 23 currencies

innovative projects (Kickstarter, My Major Company, Experiment). As, the decision of providing money or not depends on many contributors instead of one, the chances of having access to funds considerably increase for solicitors.

In addition to giving access to funds, crowdfunding platforms provide other CVPs to project initiators such as coaching, training, tutorials, workshops along with market recognition and connection with supporters. Most supporters often dispense valuable ideas and feedbacks on marketability of sponsored projects. Indiegogo pioneer in January 2015 to deliver the service *InDemand* that permits project creators take pre-orders from supporters (or else) after the deadline of their fund-raising campaigns. By doing so and for a fee of 4% plus processing expenses, they can directly sell through Indiegogo and avoid the hassle of creating and promoting a separate web storefront (Shchetko, 2015). With such services, initiators can raise money even after the funding deadline. However, this raises the question of a crowdfunding platform's mission. Some argue there are inherent differences between shopping and match making missions. Crowdfunding is basically an entrepreneurial initiative, and as such, its technical and commercial feasibilities are at stake. While pre-ordering is rather a marketing question, once an entrepreneurial project is achieved. Using the latter to support the former might be misleading.

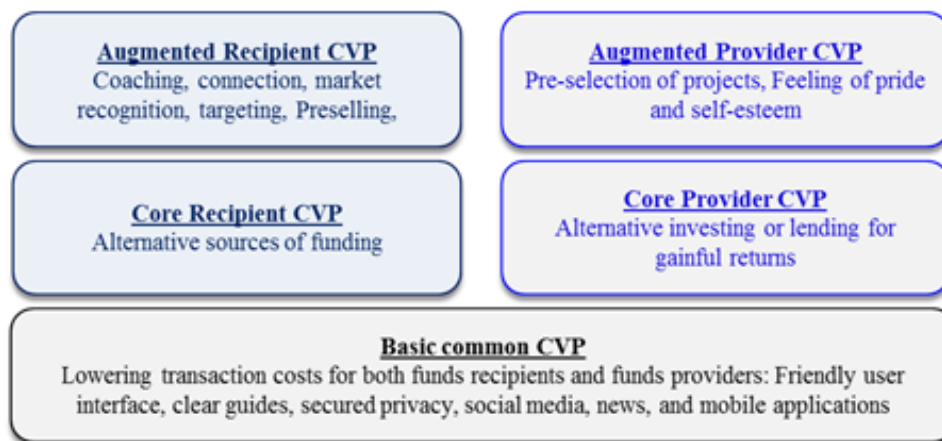

Field targeting is also another CVP some platforms provide a more pertinent matching. Examples are AngellList, Kiosk to invest and StartNext, dedicated to startups.

For contributors, the most visible CVP on crowdfunding platforms resides in an *alternative* way of investing or lending for gainful returns. In this perspective, some websites such as Zopa increase the chances of earning by proceeding to pre-selection of projects based on reliability and feasibility. Filtering brings about further confidence and attracts more contributors. Another valuable CVP for contributors

is providing the feeling of pride, fulfillment, and self-esteem by supporting well-intentioned and praiseworthy ventures they emotionally relate to.

The figure 3 recapitulates the different levels of CVPs that the crowdfunding platforms provide. As previously mentioned, a customer value is the positive difference between the benefits associated with a product and the costs (or sacrifices by) the customer bears to obtain it. Here, the different levels of CVP represent what the recipients and providers of funds expect to enjoy on the platforms, in fine, after comparing all the objective and subjective benefits and costs. It is worthy to remind that the drastic reduction of transaction costs between project leaders and backers is the founding and fundamental crowdfunding's CVP.

Figure 3. Scale of CVPs on Crowdfunding Platforms

Revenue Streams on Crowdfunding Platforms

Our analysis of the sample members shows that income streams are generally similar and mainly include commissions, processing and financial transfer fees. However, amounts might vary.

Because crowdfunding platforms essentially function as market makers, linking offer and demand, their principal revenue stream originates in commissions, payable in the case of successful fundraisings. They generally present a wide array of explanations about the commissions to make the process smoother. Rates of commission vary among websites, from usually 3 to 5 points of percentage (Experiment or AngelList) to 10 (MyMajorCompany). StartNext displays a special case. It does not set a commission but leaves the compensation for its services to the willingness of project initiator.

For projects exceeding 500,000€, Ulule charges only 5.4% with 0.25€ per transaction. However, Ulule is more expensive for campaigns of less than 500,000€ and for payments done by other means than PayPal. For instance, it charges 14.67% of the principal for a successful project of less than 100 000€, paid by credit card.

Many crowdfunding websites charge fees as well for financial processing and operations (Indiegogo, babeldoor, Startnext). Other examples of income streams are: selling regular, additional and premium products and services.

Many platforms, in particular those based on donations also look for aids from sponsors (Kiva, Babyloan for example). However, some equity-based platforms whose specialty is investing in film production similarly solicit for donations.

In the table 4, we include mainly revenues which originate in services rendered to project leaders and contributors. Therefore, revenues such as sponsorship and volunteering are not considered.

Table 3. Income streams of online crowdfunding websites

	CVP for project initiator	Platform	CVP for contributors
Credit		Kiva	No charge, donation
	Borrowers: 1 - 2% on loans	Prosper	Investors: 0.5-0.1% on credit grades
	Lenders: depending on loan amount	Babyloan	
Donation	Project initiators: 5%	Gofundme	Project initiators: fees
	Project initiators: 8%	babeldoor	Project initiators: 3% transaction
Equity	Initiators: 10%	Sowefund	Investors: 1.5%, fees
	Initiators: 5–20%	AngelList	
	Initiators: 7–9%, fees for listing	Kiosktinvest	Investors: 4%, 25€ per investment
Reward	Music 40%; others: 10% of revenue	MyMajorCo.	Contributors: 3% of payment
	Initiators: 4% on funds raised	Indiegogo	Fees: 3 – 5%
		Kickstarter	
	Initiators: 5-8% on funds raised	ulule	Contributors: Fees on transactions

Technological Infrastructure and Competencies of Crowdfunding Platforms

We have previously mentioned the importance of the Web 2.0 technologies in the infrastructure of the P2P platforms. In the analysis of the third component of infrastructural technologies and supporting competencies, we put emphasis on social media which support the crowdfunding platforms' mission of intermediation on the two-sided markets between distant recipients and providers of funds. The social media not only facilitate interactions among peers, but also contribute to the reputation of the platforms.

The members of our sample unsurprisingly promote linking between platforms and peers, but also between peers on social media such as Facebook, Google+, Instagram, Pinterest, Twitter, YouTube, etc. However, the degree of adoption and exploitation of the social media varies among platforms.

In the analysis that follows, we consider the most important current social media, Facebook, Twitter and YouTube, and distinguish between the official pages created and run by the platforms of our sample, and the unofficial or independent pages, created by independent individual who publicly express their contempt and discontent about the respective platforms.

On Facebook, platforms (Indiegogo, Kickstarter, Kiosk to invest, Sowefund, touscoprod, Ulule,) mainly report on crowdfunding in general and on their successful projects in particular. Some also do marketing promotions. The platforms regularly update Facebook pages, however some feed less their pages. The high number of “Likes” is an indicator for assessing the relationships the crowdfunding platforms manage to have with partners (Kiva, Babyloan, Indiegogo, MyMajorCompany, Ulule). There are also some independent pages for some brands on Facebook (Kickstarter & Indiegogo Worldwide

Community, Sauvons Ulule). It is also possible that a crowdfunding brand is quoted on some independent generalist Facebook pages for exemplary cases (FoodRaising on Christmas for All).

Twitter is also massively adopted by the platforms under study. Some of them have even separate Twitter pages in different languages such as Ulule, which runs its Twitter pages in English and French. This social media is often analyzed in terms of number of followers and that of tweets (messages). At the date of our study, in December 2018, the number of followers in comparison to that of February 2015, was quite impressive on Propser (20,7K; 13K), Kickstarter (1.06M; 952K), Indiegogo (341K; 202k), and Ulule (28.5K; 7K). Some others enjoy less followers in December 2018: Kiosk to invest (717). The number of tweets per follower in December 2018 has increased in comparison to February 2015, the two dates of observation, for Ulule (1,2; 0.32), and Kickstarter (48; 0,009), and decrease Kiosktoinvest (0.78; 1,05) and Sowefund (0.80, 1.11). Besides the two factors that we have analyzed here, the number of re-tweets can also be analyzed. It shows the commitment and dynamism of the followers on a brand's Twitter page. For example, on Kiva and Babyloan, similar platforms for non-interest loans to the poor entrepreneurs, the number of re-tweets seemed to be low at the time of investigation.

The sample members generally use Twitter, as they use Facebook, for informing on crowdfunding, reporting on successful projects, and in a lesser extent for promoting some particular initiatives. There are also some independent Twitter pages that juxtapose the official ones like Best of Kickstarter and in particular MMCCrazymobile that provides applications for advertising on MyMajorCompany.

YouTube, the social media of video sharing, is used by the platforms of the sample for chiefly explain crowdfunding and their concepts of crowdfunding. However, those who have channels on YouTube generally update them less than their pages on Facebook and Twitter –with the remarkable exceptions of Kiva and Indiegogo. There are many independent films on YouTube as tutorial for launching projects on different platforms such as Kickstarter, Indiegogo and ulule.

There are also independent videos for showing scams and flops.

Governance of Transactions and Relations Among Crowdfunding Actors

The crowdfunding platforms, like other cyber-merchants, considerably depend on external specialized partners for being able to focus on their core business. Without appropriate governance, platforms have to internalize diverse activities and expose to bureaucratic burden or run the risk of high costs of transactions with many external partners. In addition, the two-sided market peculiarity of crowdfunding platforms underlies even more the importance of governance. We observe different stakeholders of the platforms of our sample in four concentric circles.

If as previously mentioned, governance aims to encourage some specific behaviors and relations among stakeholders, then we can distinguish two kinds of functional and emotional relations in crowdfunding. The first one supports relations for running routine business operations. The second relates to emotional and even sensational relations around crowdfunding projects. Ignoring the specific motivation of contributors in crowdfunding can be fatal as in the examples of the American Oculus VR and of the Swedish Mojang AB which ended in public outcries in social media-despite outstanding initial success of raising funds on the Kickstarter platform.

In this perspective, we mainly focus on the second circle out of the four previously explained.

The second circle clusters project initiators and contributors for donation, lending, equity and reward crowdfunding. They are significantly different in profiles and motivations from one platform to another. Project initiators vary from scientists and researchers (Experiment), artists (MyMajorCompany), startup entrepreneurs (Angellist), musicians or even charities. Contributors also vary among platforms. They

might be donors (Experiment), professional investors, good-doers (Babyloan), reward recipients (Kickstarter, Indigogo) and professional investors (AngelList, Prosper).

We believe recognition in governance of crowdfunding platforms is crucial since even in equity and credit-based crowdfunding operations which enable considerable ROI, the primary impetus of many contributors is not profit as it is the case for professional investors. They invest or lend because they relate to and are passionate about specific exposed causes or initiatives. Motivations of stakeholders in crowdfunding are hard to detect, and treacherous to ignore. However, understanding and accommodating them is required for successfully attracting and involving them in the crowdfunding process. In this perspective, Francis Fukuyama (1992, 1995) and Axel Honneth (1996, 2002) have developed the philosophical concept of recognition.

Fukuyama's theory (1989, 1992) depicts the interplay between humans' economic desire of satisfying material needs, and the idiosyncratic desire of being recognized by other human beings at their own sense of self-worth.

For Axel Honneth (1996, 2002) the human flourishing depends on self-confidence, self-respect, and self-esteem that derive respectively from three patterns of recognition: self-confidence emerging from love in parent-child and friendship relationships, self-respect resulting from law of equal rights and self-esteem originating in solidarity and acknowledgement of personal difference and individuality.

FUTURE RESEARCH DIRECTIONS

Several research projects can support and complement the main proposal of this paper.

A first line of research will focus on projects that have raised considerable funds despite questions about their technical feasibility (Shchetko, 2014). This topic deals with the issue of governance between partners by examining how to control *ex ante* and *ex post* opportunism between initiators and contributors and how to define the responsibility and the role of the platform in this perspective.

A second line of research will look at the motivations of funders and contributors who often put more importance on the non-financial returns of the projects they support.

While researchers and observers have mainly focused on successful crowdfunding projects, a third research endeavor will explore aborted projects and identify the reasons for doing so. The hypothesis is that one learns from failure and that knowledge gained may open the door to possible future successes. The research question will be: What are the failure factors of crowdfunding? The Kickscammed platform is currently tracking problem financing projects (Fraudulent projects? Failed projects? It is not clear.).

Finally, a fourth research project will examine the impact of non-economic variables such as photo, music, and smell on the behavior of contributors.

CONCLUSION

The purpose of this paper is suggesting a theoretical business model for P2P activities and to test its validity against current platforms of crowdfunding in particular. We believe the objective is attained.

First, we identified that the P2P business model of crowdfunding is a kind of two-sided market, often called for online P2P platforms market maker, exchange facilitator, or intermediation agent.

Secondly, we proposed a quadripartite business model based four components: Customer value proposition, revenue stream, technology and competency and governance of interactions among stakeholders. The governance element is absent or discussed only briefly in the literature.

Third, we tested this theoretical model and its components against the main platforms. Observation and exploratory analysis of platforms showed that customer value is explicitly defined for project initiators and contributors on all cases. The income stream is mainly based on the commission of successful projects. The infrastructure relies heavily on Web 2.0 technologies like social media. Finally, outside of the shareholders-managers ratio, the governance of P2P platforms targets relationships between several types of partners such as owners, employees, project initiators and contributors, contractors, and public authorities.

This generic business model has important implications for P2P activities and crowdfunding. Its quadripartite framework provides a coherent way to identify the different actors that can potentially contribute to value creation and the establishment of a competitive advantage.

KEY TERMS AND DEFINITIONS

Business Model: A business model states key activities and processes to support the principles of competitive advantage the strategy defines for a firm. While a strategy defines the foundations for effective value creation, a business model outlines the specific way of creating value for them. A strategy and a business model are complementary rather than identical and required for success of P2P platforms.

Customer Value Proposition (CVP): A CVP is the worth (satisfaction, value, utility) a consumer perceives as the (positive) difference between the total benefits s/he obtains from a vendor's offering, minus the sum of pecuniary costs and non-pecuniary sacrifices that s/he has to give up in return. Customers continuously take into account competitive alternatives along with their relative benefits and costs. A CVP is always subjective and includes not only an offering's features, but also personal and social values.

Governance: Governance aims to encourage some specific behaviors and relations among stakeholders and avoid some others and relies on a third-party authority to oversight how a firm manages the interests of and relations between different internal and external parties.

Infrastructural Technologies and Competencies: A business model's component of technologies and competencies allow a firm to operate flow of goods, information, and money for delivering customer value and support competitive advantage. The Web 2.0 technologies and the competencies of using them have played a significant role in development of P2p activities by reducing the transactions costs between distant peers.

Revenue Stream: A revenue stream defines a mode of regular flow of earnings (cash-flow) that come into an organization in a period of time. Firms generally mix different income streams (revenue mix) to finance operations, investments, and rewarding shareholders and stakeholders.

Strategic Foresight Tools for Planning and Policy

INTRODUCTION

Many people in organizations believe they can foresee developments in their industry or sector. Yet, the most critical threats or greatest opportunities often emerge in other industries or sectors. Brand new trends, developments, or phenomena can emerge in adjacent fields or in society at large. Although in the beginning they may seem disconnected, they are often the drivers of change that will eventually affect one's own future, in dramatic ways.

Organizations from both the private and public sectors must improve strategic decision making to succeed in the challenging environment of today to overcome emerging complex problems, for success in an increasingly uncertain future. Strategic Foresight enables organizations to envision a range of possible future environments. Scenario-based planning then enables organizations to develop an adaptive strategy for success as the actual future unfolds.

Major corporate companies have been leveraging the power of Foresight for years. During the oil crisis of the late 1960s, Shell altered its strategy and successfully propelled itself to the top of the industry, a move credited to the use of scenario planning. Today, organizations like Intel, Ford, and Disney have joined Shell in employing futurists to leverage foresight tools for organization-wide strategy development and innovation.

Most recently, Foresight has emerged as a key instrument for the development and implementation of forward-looking research and innovation policies. Some activities show an interesting mix of approaches combining three types of elements: prospective studies of long-term opportunities and alternatives, participatory networking, and policy orientation

Strategic Foresight is well-established in many advanced economies, including the European Union, Japan, and Singapore. Among the BRICS nations (Brazil, Russia, India, China, and South Africa), Foresight programs at the government level are increasingly common.

Moreover, Strategic Foresight is about improving a leader's decision making and their ability to implement change. The practice of Strategic Foresight affects the behaviors of planning goal setting and decision-making.

Strategic Foresight enables organizations to envision a range of possible future environments. Scenario-based planning then enables organizations to develop an adaptive strategy for success as the actual future unfolds.

This paper will examine the Strategic Foresight and Scenario Planning.

DOI: 10.4018/978-1-7998-3473-1.ch056

Background

Strategic Foresight is a branch of strategic thinking, which have long been practiced in military, politics and business management for as long as the disciplines existed (Kuosa T. 2016).

The beginnings of strategic foresight military planning, strategic study and planning can be considered one of the central branches of politics and political theory. Niccolo Machiavelli can be considered as one of the first modern political strategists.

Strategic foresight was held in high esteem in Sun Tzu's book "Art of War" when he wrote, "Foreknowledge enables a wise general to achieve things beyond the reach of ordinary men".

The use of Strategic Foresight and Scenarios, in particular, to explore the future goes back to the work of Herman Kahn at the RAND Corporation in the 1950s. Kahn used scenarios to investigate different military strategies for engaging the Soviet Union during the Cold War. He became known for communicating about the future through stories told in the future.

Scenarios have been famously used to guide government policy and plans. In 1991-1992, the Republic of South Africa engaged a team from RDS to help them envision the future of RSA post-apartheid. Named after the resort where the exercise took place, four Mont Fleur scenarios were developed. The team then reverse engineered (or backcasted in futurists' terms) the decisions required along the way to achieve the future state most preferred by all stakeholders.

Strategic Planning vs. Strategic Foresight

Strategic Planning looks at what you've historically offered to members and asks, "How can we do this a little better, faster or more efficiently? How can we improve or expand upon what we're currently doing?"

Strategic Foresight looks 10 or 20 years into the future and asks, "What will our future pool members value? What kind of products and services will our members need, and how can we best serve them?"

Many Foresight professionals agree with the statement "the future does not exist" and "it is impossible to predict the future". What may fill some people with optimism, maybe a deeply depressing prospect to others? While some may focus on technological developments others may look at demographic shifts (Van der Duin P 2016).

Strategic Foresight contains a set of tools and processes for gathering systemic, participatory intelligence by pulling together a set of emerging trends underlying recent developments in a range of different sectors, together with their interactions and begin to collectively make sense of them.

Strategic Foresight and Scenario Planning

Strategic Foresight and its most common tool, scenario-based strategic planning, have been used successfully for decades in corporate planning. The most famous example is provided by the energy and petrochemical giant Royal Dutch Shell (Cardoso and Emes 2014). During the oil crisis of the late 1960s, Shell altered its strategy and successfully propelled itself to the top of the industry, a move accredited to the use of scenario planning. Today, organizations like Intel, Ford, and Disney have joined Shell in employing futurists to leverage Foresight tools for organization-wide strategy development and innovation.

Figure 1. Strategic Foresight

Figure 2. Strategic foresight and scenario planning

Strategic Foresight vs. Forecasting

Strategic Foresight should not be confused with Forecasting, which can create a narrow view of the future. “Long-term forecasting has increasingly become discredited because more often than not predictions have proved to be incorrect” (Berkhout, 2002).

Foresight is not the same as futures research or strategic planning. It encompasses a range of approaches.

- **critical thinking** concerning long-term developments,
- **debate** and for some futurists who are normative and focus on action driven by their values who may be concerned with the effort to create a wider participatory democracy.
- **shaping the future**, especially by influencing public policy.

Strategic Foresight in Practice

Strategic foresight encompasses a variety of methods, processes, and tools that assist decision makers to make sense of their complex problems with a view to guiding future-orientated decisions and planning (Vecchiato and Roveda 2010).

You gather a set of emerging trends underlying recent developments in a range of different sectors together with their interactions and start to collectively make sense of them. A vision and strategy are developed enabling leaders to make tough decisions with the future in mind.

Scenario Planning: A Strategic Foresight Tool

Foresight tools, such as scenario planning, facilitate future-orientated awareness that works by overcoming pre-existing biases, simplifying complexity, and reducing uncertainty with the aim of fostering faster and more effective decisions (Bootz 2010, Ringland 2010). Scenario planning has been used in corporate decision-making processes since the late 1970s and has been found to help make sense of uncertain environments, overcome their cognitive limitations and improve mental agility (Vecchiato 2012). Scenario planning brings together decision makers with key stakeholders who generate insights through a workshop type process as they explore the development of alternative futures (Horton 1999). Military planners even used the method in World War II to develop a series of alternative futures in an attempt to make sense of potential enemy actions (Bradfield et al 2005).

Scenario planning is a process used by organizations that wish to evaluate their readiness for the future by developing and examining the implications of a range of possible alternative futures. Scenarios are extrapolated from a detailed systematic analysis of the driving forces of change that an organization may face over the next 15 to 30 years. Strategic planning decisions are strengthened by going through the process of envisioning how current strategies and operating models would perform under different future scenarios. Crisis managers have found scenario planning a useful tool for managing uncertainty, risk, and opportunity because it provides a well-tested framework for understanding future needs and prioritizing near-term actions. Scenario planning is also a tool that places participants in a tacit knowledge environment, outside their present frame of reference, and requires them to create codified knowledge as they struggle to make sense of a new environment.

The selection and application of different scenario planning processes depend on the main characteristics of an organization’s business environment and on available expertise (Cardoso & Emes, 2014).

Strategic Foresight Methods are used in particular situations that are characterized as a Volatile, Uncertain, Complex and Ambiguous context (VUCA). Together these characteristics make the world largely unpredictable, and the future fairly unknown. In a VUCA world, traditional planning approaches do no longer provide reliable outcomes. Strategic foresight methods are designed to deal with VUCA environments.

Volatility

Volatility means that change goes up and down, just like a roller-coaster. more volatility. Second, the change can spread out to different dimensions in an unpredictable manner.

Uncertainty

In a VUCA world, there is an increase in the uncertainty about the future outcome. There are many unknowns about what will happen next. For instance, there can be uncertainty about the impact of new technology. Even with the knowledge of all the experts in the world, it is difficult to predict the outcome in uncertain instances.

Complexity

Complexity refers to a situation wherein multiple drivers of change are affecting each other. The cause and effect of change are unclear. It is unclear how the changes really interact. Complex problems tend to be wicked problems, which are ill-formulated and have incomplete and contradictory requirements. An example of a complex problem might be the war on terrorism.

Ambiguity

Ambiguity refers to the lack of clear meaning or the occurrence of mixed meanings. It is accompanied by a great potential for misreads of the situation. In sum, ambiguity is about facing the unknown.

Identifying and Mapping Change Drivers – the key trends and factors shaping the long-term development of the policy area – sits at the core of most Futures and Foresight work. Change drivers are typically characterized as the political, economic, societal, technological, legislative or environmental factors (**PESTLE**). Strategic foresight may be used to anticipate the future, innovate new products or services, or strengthen membership advantages. Strategic Foresight may be used as part of an annual Board planning meeting. Others have used it to guide work on a very important or targeted project (like starting a new line of coverage).

Approaches to the Future

Different time preferences are shown in three different approaches to the future. Predictive, explorative, and normative (Vergragt and Quist 2011); Borjeson et al; 2006). The predictive approach to the future relies heavily on historical data and projects patterns into the future. The explorative approach assumes that the future is not an automatic continuation of the past and focuses on what could happen in the future.

The normative approach is dissatisfied with the current state of affairs and views the future above all as a possibility to repair things. These three approaches are connected to cynically.

Figure 3. Scenario planning

The emergence of social media such as Twitter and Facebook illustrates the cyclical interaction between past, present, and future. This can be viewed as a historical pattern, with communication becoming ever more interactive and individual. Based on that one can think of possible future forms of social media (Duin P 2016). For instance, the Internet of Things means not only do people send tweets but objects such as cars also send tweets about their maintenance status. This image, in turn, impacts the present because businesses have to incorporate these functionalities into their existing innovation processes.

Traditional media (radio Television and newspapers) are considered fewer networks oriented and based primarily on broadcasting, whereby the past, present, and future are connected cyclically and thereby perplexing.

How Do Public Entity Pools Use Strategic Foresight?

Table 4. Strategic Foresight Six Steps: Frame the domain, scan for trends, forecast scenarios, envision the future, backcast, and implement

1. Frame The domain what is the domain you will explore?	2.Scan for forces & Trends Whom will you invite to scan? What will your scan include?	3.Forecast Scenarios what are the plausible futures in your domain?	4. Envision The future what does success look like for your domain?	5.Backcast What are the milestones you must complete to ensure success?	6.Implement what must you start now to secure your domains future?
--	--	---	---	---	--

WHAT FUTURE? FRAMING THE DOMAIN

1. Define the future you want to explore for your pool or for a specific pool initiative you want to bring focus to. Futurists call this “framing the domain.” Biting off too large a foresight project can lead to burnout.
2. Think carefully about the subject of your inquiry. What specific areas do you want to explore?
3. Three and five-year time horizons are usually too short for a foresight project to be truly strategic. Ten years is better. Twenty years is ideal. Twenty years is long enough to stretch people’s thinking and is also the length of a generation. If you are examining the future of your pool twenty years from now, you are working in a truly strategic way.

The Foresight Process: Trends Not Opinions

- (1) A trend must be increasing, decreasing, or changing in some fundamental way and must be documented by a credible source.
- (2) Engaging in deeper, unbiased thinking and might take longer than you initially anticipate.
- (3) Researching trends to be sure they’re valid, verifying a trend’s direction, and creating a solid list of trend citations can be a lot of work – but it’s important to work that pays off in terms of outcomes.

Identifying Trends: The STEEP Approach

A **STEEP analysis** is conducted when members are unsure about how the market will react to changes in particular elements.

STEEP is commonly used to gain an insight into the past, current, and future of the external environment developments during times of uncertainty, times of information overload and times of disorganization.

Figure 4. Steep approach

STEEP ANALYSIS				
Social	Technological	Economic	Environmental	Political
• Demographics • Lifestyles • Religion • Cultural values • Consumer behaviour • Advertising	• Innovation • Transport • Energy • Communication • R&D • Patent regs • Product life-cycle	• Interest rates • International trade • Taxes • Savings • Inflation • Subsidies • Employment • Entrepreneurship	• Water • Wind • Soil • Food • Energy • Pollution • Environmental regs	• Political stability • Regulation of monopolies • Tax policies • Price regulations • Consumer protection • Jurisdiction • Trade unions

SCENARIOS AND THE CONE OF PLAUSIBILITY

The Cone of Plausibility is another tool used in Foresight to help users understand that the scenarios they develop need to fall within the upper and lower limits of plausibility. If your scenarios aren't plausible, they won't be credible with your audience. Boards and management teams should ask themselves, "What scenarios are plausible?"

When the scenarios are completed, the future begins to come into view. Other questions to ask:

1. What issues or factors show up in two or more scenarios?
2. Which of these things is within our pool's control or sphere of influence?
3. Which of these things, if we managed them well, would mitigate risk or help us gain an advantage in some way?

The issues or factors that meet these criteria are your pool's transformational factors. Because they are common among multiple plausible futures, and because you can influence them to at least some degree, concentrating on these factors will help your pool no matter which possible future turns out to be closest to your actual future.

Figure 5. Scenarios and cone of plausibility

BACKCASTING: MOVING FROM THE FUTURE TO THE PRESENT

1. Begin with the end in mind
2. Move backward from the vision to the present
3. Move step by step towards the vision

The Vision

Example: By 2036, organization A will be the best place to work, recognized for its high levels of trust and collaboration among employees, members, and partners. will celebrate their tenth year in a row of being a “Best Place to Work.”

Their pool’s employee retention (not including retirements) will be 90 percent or higher. >

All member growth and retention metrics will be defined and targets will have been met for at least five consecutive years.

THE FUTURE STARTS TODAY

After backcasting and identifying milestones, next comes implementing.

For most pools, this is the easy part. Pools are experienced planners: identifying objectives, strategies, and tactics and reporting quarterly, semi-annual and annual results. Some pools use Peter Drucker’s MBO (Management by Objectives), or George T. Doran’s SMART goals (Specific, Measurable, Assignable, Realistic, and Time-related). Others might implement with a more home-grown approach.

Figure 6. Backcasting

COLLECTING INFORMATION OR SCANNING

Horizon Scanning and Searching for Weak Signals

Almost all Foresight activity starts with or involves **Horizon Scanning or Environmental Scanning**. It is a process of looking outwards, at the trends and drivers that are currently shaping the world, including those within and outside a given context. Horizon scanning is often based on desk research, helping to develop the big picture behind the issues to be examined.

Desk Research involves a wide variety of sources, such as the Internet, government ministries and agencies, non-governmental organizations, international organizations and companies, research communities, and online and offline databases and journals. Thorough horizon scanning that is both wide and deep, produces a pool of insights that form one big knowledge base about the future. Interpreting data and formulating versions of the future: This step generally consists of applying a combination of techniques and practices such as identifying weak signals or emerging strategic issues, causal layered analysis, wildcard exercises, participatory methods, road mapping, scenario planning, the **Delphi method** and so on.

Figure 7. Horizon scanning

Scenario Thinking

Scenario thinking is increasingly being used as a tool for strategizing in private and public sector organizations. The “Mont Fleur” scenario exercise, undertaken in South Africa during 1991–92, was innovative and important because, in the midst of deep conflict, it brought people together from across organizations to think creatively about the future of their country.

Transformative Scenario Planning in South Africa

Nelson Mandela was released from prison in 1991 and the negotiations to end apartheid had begun. In the midst of deep conflict, the **Mont Fleur Scenario** was an opportunity for people from different organizations and political and ideological landscapes to engage in dialogue and think creatively about the future of their country. A team consist of 22 participants South African leaders from the opposition and the establishment (left and right, black and white), business people, politicians, academics, trade unionists and community workers that imagined four scenarios in response to the question: “How will the South African transition go and will the country succeed in ‘taking off’?” In a set of informal meetings and open conversations, the scenario process enabled participants to create common ground and contributed to establishing mutual understanding. As a set, the scenarios provided a provocative roadmap for the country’s transition away from apartheid. This exercise also helped to avert an economic disaster by shifting the economic thinking and action of the African National Congress (ANC) and cementing strict and consistent fiscal discipline. Mont Fleur is a wonderful example of transformative scenario planning providing “a way for people to work with complex problematic situations that they want to transform but cannot transform unilaterally or directly” (Kahane, A). The project was important in understanding its impact. It took place during the period between February 1990, when Nelson Mandela was released from prison, and the African National Congress (ANC), Pan African Congress(PAC), South African Communist Party (SACP), and other organizations were legalized, and April 1994, when the first all-

Figure 8. Transformative Scenario Planning

race elections were held. During these years, dozens of “forums” were set up in South Africa, creating temporary structures that gathered together the broadest possible range of stakeholders (political parties, civic organizations, professional bodies, government departments, trade unions, business groups, etc.) to develop a new way forward in a particular area of concern. There were forums to discuss education, housing, economic policy, constitutional matters, and many other areas. They ranged from informal, off-the-record workshops to formal, public negotiations. The Mont Fleur project was one type of forum that, uniquely, used the scenario methodology.

The purpose of Mont Fleur was “not to present definitive truths, but to stimulate debate on how to shape the next 10 years.” The project brought together an adverse group of 22 prominent South Africans—politicians, activists, academics, and businessmen, from across the ideological spectrum—to develop and disseminate a set of stories about what might happen in their country during 1992–2002

The Five Stages of Transformative Scenario Planning

Step One: Convene a Team From Across the Whole System

Getting the right people in the team is crucial. The makeup of the team will, to a large extent, determine whether or not the project is successful.

Step Two: Observe What is Happening

The facilitators invite people to observe what is actually happening. This part can be challenging.

Step Three: Construct Stories About What Could Happen

The facilitators encourage people to construct scenarios about what they think **could** happen. Not what people predict will happen, should happen or believe will happen. As in most classic scenario planning, people are encouraged to explore the possible ways forward and the consequences.

Step Four: Discover What Can and Must be Done

This is the time for shaping the future. Instead of simply adapting to circumstances, people can focus on how to transform the future. Alan describes this in the following way.

The scenario team met three times in a series of three-day workshops at the Mont Fleur conference center outside Cape Town. After considering many possible stories, the participants agreed on four scenarios that they believed to be plausible and relevant:

- **Ostrich**, in which a negotiated settlement to the crisis in South Africa is not achieved, and the country’s government continues to be non-representative
- **Lame Duck**, in which a settlement is achieved but the transition to a new dispensation is slow and indecisive
- **Icarus**, in which transition is rapid but the new government unwisely pursues unsustainable, populist economic policies
- **Flight of the Flamingos**, in which the government’s policies are sustainable and the country takes a path of inclusive growth and democracy.

Figure 9. Mont fleur Scenarios

The group developed each of these stories into a brief logical narrative. A fourteen-page report was distributed as an insert in a national newspaper, and a 30-minute video was produced which combined cartoons with presentations by team members. The team then presented and discussed the scenarios with more than fifty groups, including political parties, companies, academics, trade unions, and civic organizations. At the end of 1992, its goals achieved, the project was wrapped up and the team dissolved.

What the Project Was and Was Not

The ideas in the Mont Fleur team's four scenarios were not in themselves novel. What was remarkable, important figures delivering the messages, and how this group worked together to arrive at these messages. The approach was indirect and the results subtle:

Mont Fleur Did Not Resolve the Crisis in South Africa

The project, along with other, on-scenario forum processes, contributed to the establishment of a common vocabulary and mutual understanding. The shared language of Mont Fleur extended beyond the

negotiating elite and was thus able to include such dialogues as an exhortation to Flamingos in a Sunday church sermon and a concern raised about Lame Duck on a rural radio phone-in. This kind of common understanding, together with many other factors, promoted agreement upon a settlement to the crisis:

Figure 10. The Logic of Mont Fleur

- The participants did not agree upon a concrete solution to the country's problems. They reached a consensus on some aspects of how South Africa "worked," on the complex nature of the crisis, and on some of the possible outcomes of the current conditions. More specifically, they agreed that, given the prevailing circumstances, certain strongly advocated solutions could not work, including armed revolution, continued minority rule (Ostrich), tightly circumscribed majority rule (Lame Duck), and socialism (Icarus). As a result of this process of elimination, the broad outline of a feasible and desirable outcome emerged (Flamingos)
- The process was not a formal, mandated negotiation. Rather, it was an informal, open conversation. At the first workshop, some of the participants expected to encounter difficulties in agreeing on anything. Over the course of the meetings, they talked until they found areas of shared understanding and agreement, several of which were relevant to the formal negotiations which were occurring simultaneously
- It did not deal with the different parties and then finding a way to narrow or reconcile these differences. The Mont Fleur process, in contrast, only discussed the domain that all of the participants had in common: the future of South Africa. The team then summarized this shared understanding of the scenarios. The aim of such on-negotiating processes is, as Marvin Weisbord, an organizational consultant, has stated, to "find and enlarge the common ground."

Results From the Project

The Mont Fleur project produced several different types of results: substantive messages, informal networks, and understandings, and changed ways of thinking. The primary public output of the project was the group of scenarios, each of which had a message that was important to South Africans in 1992:

- The message of Ostrich was that a non-negotiated resolution of the crisis would not be sustainable. This was important because elements of the National Party (NP) government and the business community wished to believe that a deal with their allies, instead of negotiation with their opponents, could be sufficient. After hearing about the team's work, NP leader F.W. de Klerk was quoted as saying, "I am not an Ostrich."
- Lame Duck message was that a weak coalition government would not be able to deliver and therefore could not last. This was important because nature, composition, and rules governing the Government of National Unity (GNU) were a central issue in the pre-election negotiations. The NP wanted the GNU to operate subject to vetoes and other restrictions, and the ANC wanted unfettered "winner takes all" rules. Lame Duck explored the boundary in a GNU between compromise and incapacitation.
- Icarus warned of the dangers of a new government implementing populist economic DEEPER S2 policy. This message—coming from a team which included several of the left's most influential economists—was very challenging to the left, which had assumed that government money could be used to eradicate poverty quickly. The business community, which was worried about Icarus policies, found the team's articulation reassuring. The fiscal conservatism of the GNU was one of the important surprises of the post-election period.
- The simple message of Flight of the Flamingos was that the team believed in the potential for a positive outcome. In a country in the midst of turbulence and uncertainty, a credible and optimistic story makes a strong impact. One participant said recently that the main result of the project was that "We mapped out in very broad terms the outline of a successful outcome, which is now being filled in. We captured the way forward of those committed to finding a way forward."

The Mont Fleur Project was the creation of informal networks and understandings among the participants—an influential group from across the political spectrum—through the time they spent together. These connections were standard for this forum period, and cumulatively provided the basis for the subsequent critical, formal agreements.

Lastly—the least tangible yet most fundamental—was the change in the language and thought of the team members and those with whom they discussed their work. The Mont Fleur team gave vivid, concise names to important phenomena that were not widely known, and previously could be neither discussed nor addressed. At least one political party reconsidered its approach to the constitutional negotiations in light of the scenarios.

WHAT THE MONT FLEUR PROJECT ACCOMPLISHED

The Scenario Process Was Logical, Open and Informal

In the first Mont Fleur workshop, a story about the Chinese Red Army helping to liberate South Africa fell away on these grounds, rather than on the basis of preferences. Building Scenarios can be creative because the process is “only” about telling stories, not about making commitments. This allows people to discuss almost anything, even taboo subjects.

The Scenario Process was Inclusive and Holistic

A story about the future must be able to encompass all aspects of the world: social, political, economic, cultural, ecological, etc. Moreover, the process of telling several stories encourages people to surface and listen to multiple perspectives. In discussing a fundamentally unpredictable future, there is no one truth.

The Process Elicits Choices

One of the premises of scenario thinking is that the future is not predetermined and cannot be predicted.

Transformative Scenario Planning Helpful with the Following Three Characteristics

1. The participants in the Mont Fleur project, for example, viewed apartheid as unacceptable, unstable, and unsustainable, and saw the just-opened political negotiations as offering them an opportunity to contribute to changing it.
2. Participants cannot transform their situation on their own or by working only with their friends and colleagues. Even if they want to, they are unable to impose or force through a transformation. They must find some way to work together with actors from across the whole system. South Africans who wanted to transform the apartheid situation had been trying for decades to force this transformation, through mass protests, international sanctions, and armed resistance. But these efforts had not succeeded. Mont Fleur and the other multi-stakeholder processes of the early 1990s (which the previous forceful efforts had precipitated) provided South Africans with a new way to work with other actors from across the system.
3. The situation cannot be transformed directly. The actors who need to work together to make the transformation are too polarized to be able to approach this work head-on. They agree neither on what the solution is nor even on what the problem is. They did agree that they face a situation they all find problematic, although in different respects and for different reasons. Any attempt to implement a solution directly would therefore only increase resistance and rigidity. So the transformation must be approached indirectly, through first building shared understandings, relationships, and intentions.

The actors who came together in Mont Fleur all agreed that apartheid was irretrievably problematic and needed to be dismantled, but they came in with deep differences in their diagnoses of the ways in which it was problematic and their prescriptions for how it should be transformed. The scenario process enabled them to create common ground. In the community example, the administrators, teachers, parents,

and students might have a long history of unproductive disagreements that means they cannot simply sit down and start to work together.

Transformative Scenario Planning is, then, a way for people to work with complex problematic situations that they want to transform but cannot transform unilaterally or directly. The Mont Fleur participants constructed a new way of understanding the political, economic, and social challenges that South Africans were facing and then created four scenarios as to how South Africans could try to deal with these challenges. The participants constructed new relationships and alliances, especially between leaders of hitherto-separated parties, sectors, and races. And they constructed new intentions as to what they needed to do in their own spheres of influence to try to prevent the “Ostrich,” “Lame Duck,” and “Icarus” scenarios and to bring forth “Flight of the Flamingos.” Over the years that followed, these new understandings, relationships, and intentions enabled the participants and others with whom they engaged to undertake a series of aligned actions that did, in fact, contribute to their achieving these intentions.

Figure 11. *Flight of The Flamingos*

Transformative scenario planning can generate transformations such as those in these two examples only if three components are in place. Transformative scenario planning is a composite social technology that brings together three already-existing technologies into a new way of working that can generate new results. If any one of these components is missing, this new way of working will not work.

The first component is a *whole-system team* of insightful, influential, and interested actors. They choose to join this team because they think that if they can act together, then they can be more successful.

The second component is a *strong container* where actors can transform their understandings, relationships, and intentions. The political positioning of the exercise, so that the actors feel able to meet their counterparts from other parts of the system without being seen as having betrayed their own part;

the psychosocial conditions of the work, so that the actors feel able to become aware of and challenge (and have challenged) their own thoughts and actions; and the physical locations of the meetings, so that the actors can relax and pay attention to their work without interruption or distraction.

The third component is a *rigorous process*. In a transformative scenario planning process, the actors construct a set of relevant, challenging, plausible, and clear stories about what *could* happen—not about what *will* happen (a forecast) or about what *should* happen (a wish or proposal)—and then act on what they have learned from this construction. The uniqueness of the scenario process is that it is pragmatic and inspirational, rational and intuitive, connected to and challenging of dominant understanding, and immersed in and disconnected from the complexity and conflict of the situation. Furthermore, the future is a more neutral space about which all actors are more equally ignorant.

The transformative scenario planning process that was invented at Mont Fleur originated in the adaptive scenario planning process that had been invented at Shell two decades earlier— In an adaptive scenario planning process, the leaders of an organization construct and employ stories about what could happen in the world outside their organization in order to formulate strategies and plans to enable their organization to fit into and survive and thrive in a range of possible futures.

Adaptive Scenario Planning

Adaptive scenario planning is useful only up to a point. Sometimes people find themselves in situations that are too unacceptable or unstable or unsustainable for them to be willing or able to go along with and adapt to. In such situations, they need an approach not simply for anticipating and adapting to the future but also for influencing or transforming it. For example, an adaptive approach to living in a crime-ridden community could involve employing locks or alarms or guards, whereas a transformative approach could involve working with others to reduce the levels of criminality.

An adaptive response to climate change could involve building dikes to protect against higher sea levels, whereas a transformative approach could involve working with others to reduce emissions of greenhouse gases. Both approaches are rational, feasible, and legitimate, but they are different and require different kinds of actions and alliances.

Adaptive Scenario Planning vs. Transformative Scenario Planning

The key difference between adaptive and transformative scenario planning is, then, one of purpose. Adaptive scenario planning uses stories about possible futures to study what could happen, whereas transformative scenario planning assumes that studying the future is insufficient, and so it also uses stories about possible futures to influence what could happen. To achieve these two different purposes, adaptive scenario planning focuses on producing new systemic understandings, whereas transformative scenario planning assumes that new understandings alone are insufficient and so also focuses on producing new cross-system relationships and new system-transforming intentions. Adaptive scenario planning requires a rigorous process, whereas transformative scenario planning assumes that process alone is insufficient, and so it also requires a whole-system team and a strong container.

Transformative Scenario Planning and The U Process

Five steps can be framed as an application of the U-Process to the transformation of complex problematic situations. The U-Process is a model of transformation that includes five movements: initiating (in

transformative scenario planning, this is the convening step), cosensing (the observing and constructing steps), co-presenting (the discovering step), and co-creating and coevolving (the acting step). The U-Process is an indirect process—a detour—in that it is a way to get unstuck and move forward to transform a problematic situation through pausing and stepping back from the situation. It is a creative process in that what can and must be done on the right-hand side is not visible from the left-hand side but can be discovered only along the way.

Transformative scenario planning is simple, but it is not easy or straightforward or guaranteed. The process is emergent; it almost never unfolds according to plan, and context-specific design and redesign are always required. So the only way to learn this process is to practice it in a range of contexts.

Challenges and Limitations

Due to methodological constraints, foresight is often too theoretical and abstract for non-practitioners. The transmission of knowledge to policymakers operating with different cultures, vocabularies, processes and time scales is one of the biggest difficulties futurists face. As a result, “much foresight work, while very interesting and great fun to discuss over dinner, goes unused, unappreciated, and makes little observable difference” (Horton, 2012). Long-term futures also tend to seem dystopian or unrealistic to people and careful engagement is required in order to inform policymaking.

Foresight and Policy Making

Foresight and policymaking decision makers are often tasked to deal with short-term urgencies, as well as plan for long-term sustainable development. This is particularly challenging in developing countries where resources are limited and budgets and capabilities must be prioritized. What is the relationship of foresight to policy making? “In the best cases, foresight activities will initiate changes in the way decisions are made and policies are designed” (Da Costa, 2008). It offers a long-term view: “As a factor in governance, the purpose of foresight is to enhance the ability of decision-makers to engage and shape events at a longer range and, therefore, to the best advantage of the citizens they serve” (Fuerth, 2009). The biggest difficulty, however, is to get the message across to decision-makers, so that they most effectively use the foresight results.

Policymakers may sometimes be blindsided by ‘**black swans**’, ‘unknown unknowns’ and ‘**wild-cards**’ because traditional forecasting methods are based primarily on linear extrapolation. Foresight practitioners, however, are more comfortable with a non-linear world. Policymakers are dealing with increasingly complex, multidimensional issues that are frequently interconnected and interdependent. In today’s global environment, events and trends in various spheres interact with one another in complex and sometimes mystifying ways.

Complex Problems Simplified with Strategic Foresight and Scenario Planning

Short-term endeavors may rely on forecasting, whereas foresight is more suitable for mid to long-duration projects. Complexity refers to how easy or difficult it is to understand the relationships between an issue’s driving forces and uncertainties. Issues with clear, visible cause-and-effect relationships are designated simple or low complexity, while high complexity issues are those in which the cause-and-effect between driving forces and uncertainties are not fully visible or well understood or known. to how easy or difficult it is to understand the relationships between an issue’s driving forces and uncertainties. Issues

with clear, visible cause-and-effect relationships are designated simple or low complexity, while high complexity issues are those in which the cause-and-effect between driving forces and uncertainties are not fully visible or well understood or known.

Complex problems are interconnected and interdependent issues that might exist in different spheres, but interact with each other in unpredictable and sometimes mystifying ways. Complex systems are also the seedbed of ‘unknown unknowns’, ‘wildcards’ and ‘black swans’, which ultimately generate ‘wicked problems’. Wicked problems are large, intractable challenges with many dimensions and multiple stakeholders who may have divergent goals. They have no immediate or obvious solutions and their causes and influencing factors are not easily determined, so they have no simple solutions. Today’s wicked problems include climate change, energy security, global pandemics, terror networks, and extreme poverty.

Solutions and Recommendations

Foresight practitioners must overcome the gap between themselves and decision makers. This may be achieved if Foresight practitioners align their work with national political agendas and ongoing administrative processes, which allows them to more effectively feed their results into the appropriate political channels. Complex problems resulting from modern challenges like reforming the United Nations, Private Sector Engagement and Human Rights have renewed their appetite for Foresight practices that can describe the systemic change. Decision makers must also be aware of the crosscutting implications of policy effects in seemingly unrelated areas. In order to deal with such unintended consequences policies across the board must be adaptable and resilient to potential change, disruptions or shocks.

Future Research Directions

Foresight practitioners are beginning to adopt a new approach dubbed Human-Centered Foresight, using methods employed by designers to predict the future, starting with the ‘users’. based on a traditional design approach, human-centered foresight begins by thinking about the future from the center of the issues; identifying who the users are, what their interests are and how those might collide with changing external factors.

Properly facilitated, there is a potential for policymakers in low-capacity countries to develop long-term, sustainable development policies by collaborating with independent foresight academics, practitioners, and institutions producing current research.

CONCLUSION

Without Strategic Foresight, an organization may have a good understanding of the short-term trends in their industry, or even general long-term trends in society. But, in an interconnected world where change is occurring ever more rapidly, and where the boundaries between industries are blurring, more is needed.

What happens on one side of the world has an impact on the other side of the world. A small startup today may disrupt the largest company in the world tomorrow. Political instability can change the balance of power and have widespread consequences across the globe. Fortunately, with these topics dominating conference agendas and coffee table discussions, systematic foresight activity has gained momentum.

More and more organizations want to understand in greater detail how the world is changing and how they can make the most of these changes. On 22 January 2019 in Sarajevo, Bosnia-Herzegovina (BiH),

the EUISS (European Union Institute For security Studies) organized a strategic foresight workshop for representatives from the EU Special Representative in BiH (EUSR), the Delegation of the EU to BiH and EUFOR Operation Althea. The strategic foresight workshop is an example of the EUISS' continued efforts to strengthen the EU's analysis, foresight and networking capacities in external action. Strategic Foresight is to help them in that difficult task.

KEY TERMS AND DEFINITIONS

Backcasting: A planning method that starts with defining a desirable future and then works backwards to identify policies and programs that will connect that specified future to the present. The fundamentals of the method were outlined by John B. Robinson from the University of Waterloo in 1990.

Black Swan: An event or occurrence that deviates beyond what is normally expected of a situation and that would be extremely difficult to predict.

Horizon Scanning: A systematic process that serves as an “early warning system” to inform decision-makers about possible future opportunities and threats. It identifies technologies, innovations, and trends with the potential to cause future disruptions, both positive and negative.

Lame Duck: An outgoing politician is an elected official whose successor has already been elected or will be soon. The official is often seen as having less influence with other politicians due to the limited time left in office.

Scenario Planning: Also called scenario thinking or scenario analysis, is a strategic planning method that some organizations use to make flexible long-term plans. It is in large part an adaptation and generalization of classic methods used by military intelligence.

Strategic Foresight: Also known as Futures Studies, is discipline organizations use to gather and process information about their future operating environment. This information can include, for example, trends and developments in their political, economic, social, technological, and legal environments

U Process: Developed by Otto Scharmer to provide a language for exploring different ways of being in the world. To transform your habitual ways of doing things you have to see them differently with an open mind and open heart. At a point of quiet, deep reflection where we become totally focused on being present and available to our intuition or inner voice.

Wild Cards: In futurology, future research, horizon scanning, and foresight, wild cards are low-probability, high-impact events. This concept may be introduced into anticipatory decision-making

activity in order to increase the ability of organizations and governments to adapt to surprises arising in turbulent (business) environments.

INTRODUCTION

The concept of strategic planning came to prominence in the 1980s under the banner of New Public Management; since, several of the private sector components of strategic planning have been applied and interpreted within the public sector. While many of the concepts were not new, the application to the public sector was. The rise and general acceptance of public sector strategic planning also coincided with the digital revolution beginning in the late 1980s, offering enormous promise, but also an equal number of potential pitfalls. As the digital era became increasingly sophisticated, new possibilities emerged for governance and strategic planning.

The rise of the internet in the mid-1990s changed public sector planning from an almost exclusively hierarchical entity, into a series of interconnected networks. Hierarchical authority was still prevalent, but gradually the lines of authority, and in turn accountability, had been increasingly blurred amongst a growing number of actors. The further technological innovations have had major implications on government and governance structures, and the strategic planning process is critical in promoting innovation, growth, and effectiveness (Arend, Zhao, Song, & Im, 2017).

This entry explores the development of public-sector strategic planning, specifically the impact of technology and how strategic planning has grown throughout the digital era; along with potential opportunities and challenges moving forward as technology and organizational dynamics continue to evolve.

BACKGROUND

What is Strategic Planning?

Strategic planning is more than just another concept taken from the private sector to increase public sector efficiency (Hendrick, 2003). Strategic planning is a “deliberative approach and set of concepts, procedures, and tools that can help leaders to enhance the achievements of their organization” (Bryson, 2011, p. xiv). Strategic planning has become widespread throughout all levels of government in the United States over the last 25 years, and the growth of technology has only helped to stimulate it even further (Berry & Wechsler, 1995; Bryson, 2010; Bryson, Berry, & Yang, 2010; Bryson, Crosby, & Bryson, 2009; Hendrick, 2003; Poister, 2010; Poister, Pitts, & Edwards, 2010; Poister & Streib, 2005).

The importance of technology to organizations to inform both research and practice has long been realized; however, there has been little widespread agreement over how to best utilize and measure the

DOI: 10.4018/978-1-7998-3473-1.ch057

impacts of technology on organizations (Orlikowski, 1992). Orlikowski and Barley (2001) suggest that to understand the ongoing innovations taking place in government it is imperative to understand both the technological advances and the institutional structures.

How to understand and best leverage the changing nature of technology is a question that will come up repeatedly throughout this review. In addition to the role of and questions over technology, debate exists over what makes up strategic planning and ultimately how encompassing it should be. Bryson (2011) explains it as the overarching, umbrella concept under which strategic thinking, acting, learning, and deliberation fall. These activities make up the most important components of strategic planning (Bryson, 2011) and collectively these activities provide an organized process for gathering information on a large scale and using it to determine a long-term direction (Poister & Streib, 2005). Strategic planning is a short-term planning strategy necessary to help ensure long-term success (Poister & Streib, 2005). It is a management tool that takes inventory of organizations' strengths and weaknesses, as well as opportunities and threats and how best to take advantage of the positives while mitigating the negatives (Denhardt, 1985; Kissler, Fore, Jacobson, Kittredge, & Stewart, 1998). Strategic planning is ultimately a way to meet the needs of the citizenry through improved performance and better service (Boyne & Walker, 2010). As government at all levels has moved away from traditional hierarchical structures toward more responsive networked agencies, strategic planning has become an increasingly used tool for governance (Berry, 1994) in an effort to enhance digital connectivity and socio-economic progress (Alam, Erdiaw-Kwasie, Shahiduzzaman, & Ryan, 2018).

Contrary to the widespread public sector support, there have been numerous criticisms attached to strategic planning. For one, strategic planning is not a panacea; strategic planning is not guaranteed to improve performance, and the point is not to create rigid channels and structures that trigger specific repeatable responses (Bryson, 2011). The inherent flexibility that characterizes strategic planning, and the efforts of strategic planning to produce real change often turns into one of critics most frequent complaints; strategic planning is hard to define, even harder to measure, and perhaps most difficult to determine who it is responsive to (Bryson, Crosby, & Bryson, 2009; Bryson & Roering, 1989; Kissler, Fore, Jacobson, Kittredge, & Stewart, 1998; Mansor & Tayib, 2012). The lack of a clear definition can be attributed to the changing nature of policy and the needs of the community; new issues emerge, outcomes are difficult to discern, significance is unclear, and goals fluctuate. Nonetheless, strategic planning is a tool that provides a certain level of assurance and preparedness to public sector officials (Kissler, Fore, Jacobson, Kittredge, & Stewart, 1998). Many critics highlight these concerns and continue to treat strategic planning as a fixed object instead of a system comprised of many interacting and changeable parts (Bryson, Crosby, & Bryson, 2009).

In taking this approach it is easy to overlook the progress and evolution of the strategic planning process. Strategic planning is generally accepted to include, "clarifying mission and values, developing a vision of the future, analyzing external challenges and opportunities, assessing internal strengths and weaknesses, developing strategic goals and objectives, identifying strategic issues, developing and evaluating alternative strategies, and developing action plans" (Poister & Streib, 2005, p. 46). What ends up mattering the most "is the degree to which it (strategic planning) focuses the organization on what is important, orients the organization to identification of strategic issues, and develops the internal process where strategies and priorities are established" (Abels, 1989, p. 294).

The Early History of Strategic Planning

Strategic planning as a management tool is a relatively recent phenomenon, proliferating in the private sector during the early part of the twentieth century and not appearing with regularity in the public sector until Luther Gulick contributed POSDCORB to the Brownlow Commission in the late 1930s. It was not until the late 1950s and early 1960s that strategic planning truly began to gain traction (Bryson, 2010). Many attribute the growth to the programs instituted during the Kennedy administration by Defense Secretary Robert McNamara (Young, 2003). The goal was to increase department efficiency through planning, while still addressing long-term agency needs (Young, 2003). Vietnam notwithstanding, McNamara's effort to implement strategic planning was generally successful and did not go unnoticed. Multiple states and municipalities began to pick up on and utilize the planning and efficiency principles adopted by McNamara in the Department of Defense (Borins, 2010; Young, 2003). These efforts have led some to refer to Defense Secretary McNamara as the "godfather" of public sector strategic planning (Borins, 2010).

Strategic Planning in the Public Sector

While strategic planning began to come to prominence in the 1960s within the federal government, its prevalence across the country was still quite small. It was not until the early 1980s through a series of economic, political, and societal events leading to significant governmental reform, that strategic planning began to be utilized frequently throughout multiple levels of government (Berry & Wechsler, 1995; Bryson & Roering, 1988; Denhardt, 1985; Hendrick, 2003). The Reagan-era market reforms that ushered in what came to be known as New Public Management turned out to be a major catalyst for the rise in public sector strategic planning due to their emphasis on greater efficiency through market-like reforms. Prior to this point, much of the planning taking place was done through capital budgeting and comprehensive city planning, which as Bryson (2010) points out was far from comprehensive. The Reagan-era reforms coupled with increasing attention brought by multiple authors in the early 1980s about how private sector planning could be applied within the public sector helped to spur a new era of truly comprehensive municipal government planning (Bryson, 2010). Strategic planning became "the" new innovative strategy in public management, "promising public agencies the benefits of a rational and highly structured, future-oriented management technique borrowed from the best run private sector companies" (Berry & Wechsler, 1995, p. 159). All the while this systematic, self-analyzing strategy was revolutionizing public sector planning, technology lagged behind. By the early to mid-1980s computers were available but hardly at the same price point or level of functionality that we enjoy today. For the most part the technology remained quite like that utilized by Defense Secretary McNamara nearly two decades prior. While greeted enthusiastically by the public sector, individuals were still voicing numerous complaints about time, measurement, accountability, and actual use and value of strategic plans (Berry & Wechsler, 1995).

The Beginning of the Digital Revolution

Strategic planning began to gain a foothold at a time of great upheaval in the public sector. As Denhardt (1985) notes, the social and technological changes overtaking the country and the world in the late 1970s and early 1980s led to increasing turbulence and complexity for government. The diversity of the challenges, ranging from the oil crises of the 1970s, changing demographics and values, inflation, and

a further outsourcing and devolution of traditional government responsibilities had a profound effect on government service delivery and both technological and organizational form and function (Bryson & Roering, 1988; Orlikowski, 2000). These changes, highlighted within the New Public Management reforms of the 1980s, further outlined the need for effective strategic planning (Bryson & Roering, 1988).

The problem seemed to become not whether strategic planning was a good idea, but how to carry it out effectively (Bryson, Crosby, & Bryson, 2009; Bryson & Roering, 1989; Kissler, Fore, Jacobson, Kittredge, & Stewart, 1998; Mansor & Tayib, 2012). The beginning of the digital revolution in the mid to late 1980s, characterized by the growth of the personal computer, began to answer this question by further altering traditional forms of government and offering multiple tools to make strategic planning more accessible and impactful within the public sector. This massive growth in technology revolutionized information systems, transporting it from a task primarily centered on “efficient data processing” to one viewed as increasingly “central and critical to an organization’s growth and survival” (Venkatraman, 1985-86, p. 66). This growth in computer and communication technology and the resulting possibilities unlocked through information systems and data collection and analysis further cemented the need for full-on public sector strategic planning. As Venkatraman (1985-86) states this significant investment and the “increase in resource commitment requires systematic planning approaches for ensuring that the resources are deployed both efficiently (in the short run) and effectively (in the long run)” (p. 67). The vast increase in information technology transformed strategic planning. With technological advances came a number of additional challenges, namely how to incorporate and evolve information technology from its traditional role as an “administrative support toward a more strategic role within an organization” (Henderson & Venkatraman, 1999, p. 472).

The rapidly changing nature of government and technology in the digital age led to many reforms crucial to the success and popularity of strategic planning, but perhaps none more so than the Government Performance and Results Act of 1993 (GPRA) (Poister, 2010). This act, under the Clinton Administration’s National Performance Review, required all federal agencies to engage in periodic strategic planning practices (Poister, 2010). As Berry (1994) notes there were more than 250 state agencies in nearly every state already engaging in strategic planning activities during the 1980s. With the passage of the GPRA this number increased exponentially not just in the required federal agencies, but in state agencies as well. Berry and Wechsler, (1995) in a national survey of state agencies found that nearly 60 percent of respondents were using some form of strategic planning and of those not, nearly nine percent had plans to do so in the future. Of those polled, 47 percent began using strategic planning from 1985-1989 and an additional 39 percent instituted programs from 1990 to the time of the polling (Berry & Wechsler, 1995). By 1997 as required by the GPRA, all federal agencies were conducting strategic planning; however, the nagging question of strategic alignment remained. Specifically, individuals were still questioning how to best incorporate and make use of information and communication technology that was critical to the effectiveness of strategic planning (Henderson & Venkatraman, 1999). At the federal level, it was very much an unbalanced effort, as some agencies dove in headfirst and others simply scraped by meeting the minimum requirements for compliance. This led to further mixed efforts and something of a carrot and stick approach in which the government attempted to update regulations to provide enough incentive to get as many agencies as possible to engage in strategic planning in a manner that would result in more than just compliance but effective and meaningful strategic planning.

The Growth of the Internet and Email

The growth of the internet and email has had a profound effect on how government works. Much like the Reagan-era reforms a decade prior, the information age ushered in by an increasingly connected society posed substantial challenges to the traditional ways of governance. The economy was reshaped by the advent of new technology, which also led to increasing global markets, and a much more interconnected world and marketplace (Kissler, et al., 1998). This period of innovation highlighted the role that technology can have in reshaping society and the challenges resulting from such innovation. Bryson, Berry, and Yang (2010) attribute these challenges to the growth of the internet, stating that it is “transforming the nature and patterns of public service; therefore, strategic management must reflect this reality” (p. 511).

As society has become increasingly globalized and networked, much of the challenge and potential for strategic planning and organizations lies in “information and communication technology advancement” (Bryson, Berry, & Yang, 2010, p. 511). Information technology strategic alignment has evolved from a task of managing resources to one that attempts to determine how to leverage internet based strategic technologies to “enhance efficiency, service quality, democratic participation, and seamless e-governance” (Yang & Melitski, 2007, p. 428). By increasing participation and communication amongst stakeholders, organizations are increasingly likely to ensure individuals are on the same page and there is some level of goal congruence (Ketokivi & Castaner, 2004). In order to achieve goal congruence, “organizations have to find appropriate relationships between the ‘entrepreneurial’ problem (which strategy to adopt), the ‘engineering’ problem (which technologies to use), and the ‘administrative’ problem (which processes and structures to select)” (Boyne & Walker, 2010, p. S188). Balancing these problems in a way that will effectively give credence to each has become increasingly difficult in an era of constant innovation and online technology. Borins (2010) expresses concern that using technology to make strategic planning broad based and accessible may also open it up to further manipulation and political manipulation. Whereas Holley, Dufner, and Reed (2004) raise the concern that by balancing out such problems raised by Boyne and Walker (2010) through technological innovation, it could potentially lead to what they term “islands of information” (p. 106). These “islands” are basically systems characterized by uncoordinated information technology and communication in which information systems fail to communicate with each other; either there are compatibility issues, or the information systems simply exist as redundancies (Holley, Dufner, & Reed, 2004, p. 106). This “computerization” of the planning process has been “highly controversial” and the balancing act of using information systems effectively and integrating them properly into the planning process has raised several additional issues for planners (Poister, 2010, p. 247).

Representational diversity is one such problem (Borins, 2010). Borins (2010) calls the representational issues one of “the main challenges for online strategic planning” (p. 221). At issue is how those engaging in the strategic planning process, ensure there is a diverse representation of the population (Borins, 2010). Maintaining diversity comes down to ensuring that equal voice is given to all involved and that regional demographics and population differences are accounted for (Borins, 2010).

While the challenges are many, the effective use of information and communication technology in the strategic planning process can be highly beneficial for a given organization. Information and communication technology “may be used to achieve greater government efficiency, better service quality, and more democratic participation” (Bryson, Berry, & Yang, 2010, p. 511). Environmental assessments (Denhardt, 1985), information retention and storage, as well as faster and easier feedback mechanisms are just some of the many benefits of utilizing information and communication technology in strategic planning.

Even with the vast potential of the internet for strategic planning, many organizations had yet to effectively figure out how to harness and take advantage of such technology when it was first becoming available. Many strategic plans were internal, and organization centric, prioritizing concerns of internal efficiency over transparency, engagement, and openness (Yang & Melitski, 2007). This lag between effective incorporation of technology and the planning process is one that severely hampered the potential of the technology for strategic planning. While the rise of the internet and email has led to greater attention given to the use of technology in the strategic planning process, the complexity and prevalence of multiple factors including politics, conflicting goals, and conflict have severely hindered the scale and effectiveness of public sector strategic planning (Bryson, Berry, & Yang, 2010).

While public sector strategic planning has increasingly turned to information and communication technologies, the debate early on was centered mainly on whether the internet would be a blessing or a curse for democracy (Barber, 2001). While great progress has been achieved, especially when compared with a decade prior, setting long-term strategic goals and effectively estimating the potential of new technologies has proven to be a difficult balance (Vishnevskiy, Karasev, & Meissner, 2016).

The Social Media Era

The social media revolution that has occurred over the last decade has seen the transition of the internet from a static mechanism to a large, thoroughly integrated platform. Strategic planners who were hesitant to embrace the internet and technology were left little choice after the success and restructuring of online networks in the wake of the dot-com bubble bursting. The resulting innovation further pushed technology forward by promoting greater involvement and connectedness through open-source collaboration (O'Reilly, 2005).

With the growth of social media, starting predominantly with Facebook and Twitter, and moving into several new and intriguing directions has afforded public administrators with multiple tools to utilize in order to impact and ease the strategic planning process through greater transparency, participation, and data storage and dissemination abilities (Bryson, 2011). While Facebook and Twitter were created as social networking services for individuals to connect and share, it was not long before private-sector entities began to leverage these networks for their business goals. As innovation in the public sector is often slower and more deliberate than in the private sector, it has only been recently that many public sector organizations have begun to follow private sector leads in utilizing social media technologies in the strategic planning process. Bryson (2011) highlights the many potential benefits, but Magro (2012) cautions that a careful and cautious approach is necessary in order to avoid the potential challenges brought on by a fast-moving online environment.

Many government agencies have begun to employ social media in the strategic planning process. The census bureau is just one example in which the agency employs and maintains several social media platforms to receive feedback and communicate with individuals to help inform the planning process on a continual basis (Desouza & Bhagwatwari, 2012). While there has been significant progress within the federal government in employing social media for planning and transparency initiatives, the results have been more uneven at the state and local levels (Magro, 2012).

Ultimately the marriage of strategic planning and social media through the evolution of technology is one that shows great promise but will take time and training to best utilize new and evolving technologies in a strategic manner (Fleck & Bryson, 2011; Magro, 2012). While significant research is needed to determine how to best align social media practices with effective strategic planning, if policy makers are able to keep up, the potential is undeniable (Magro, 2012).

Crowdsourcing

Another opportunity for public sector planners is the rise of crowdsourcing. First referenced in print in 2006 by Jeff Howe in an article for *Wired Magazine*, crowdsourcing is a form of open-source collaboration, where individuals bounded by support of an idea come together through several technological channels in support of the idea. Crowdsourcing began to gain traction in the private sector with the success of *Kickstarter* and *Indiegogo* right around the time of the Great Recession. As the community has continued to grow, public sector involvement has increased. Many of the platforms, often pitched as a faster and more efficient way for municipalities to deliver goods and services to constituents, change the existing budget/funding/planning dynamics of government and allow consumers to support and fund the programs they believe in.

SOLUTIONS AND RECOMMENDATIONS

Under the auspice of the public administration paradigm of New Public Management, the concept of strategic management sought to provide a solution to the established tactical and operational mindset firmly grounded within traditional bureaucratic organizations. Considered to be a product that assists in collaborative forecasting and the creation of short- and long-term goals within the private sector, strategic planning slowly assimilated into the public sector to promote both the establishment of organizational objectives and efficiency. Whereas the establishment of an agency mission and objectives through strategic planning has dramatically improved the planning and operational capabilities within the public sector, multiple challenges were faced throughout both the sectoral assimilation and acceptance process. Although widely embraced through multiple sectors, strategic planning was never dynamically conceptualized to integrate new methods of collaboration and facilitatory technology established after cultural and societal changes. The current shifts in knowledge and information management within the strategic planning process from a team-centric to a broader organizational perspective also challenges the methodology of how technology was utilized to obtain information for strategic management activities.

Although strategic planning has developed into a universal instrument for charting the course for public and private sector agencies over the past several decades, the dynamic organizational environment of tomorrow presents a challenge to the current broad definition attributed to strategically planning for an organization's future. Sampler (2014) argued that the current concept of strategic planning is obsolete due to the rapid rate of change, the complex networks and collaborations replacing traditional hierarchical organizations, and the adaptive work needs to press forward with less reliance on past practices and performances. Bryson, Edwards, and Van Slyke (2018) justified the position of obsolescence, as the current conceptualization of strategic planning involves a rigid framework based upon standard procedures and an analysis of past performance measurements for current operations.

Strategic planning is often perceived as an act of setting the course utilizing current knowledge, skills, and experiences. In an effort to align strategic planning with the complexities of the unknown future, Bryson et al. (2018) posited that strategic planning should be viewed as a function that focuses on a "temporal horizon" (p. 327) rather than concrete objectives that may have been developed utilizing limited and skewed foresight. The functional definition of strategic planning, when supplemented by open input and discourse, may help to compensate for the human mind's inability to engage in the rational forecasting of unknowns.

Bolisani and Bratinu (2017) advised that collective organizational knowledge may be used to supplement the gap between the limited rationality of decision-makers and the dynamic and uncertain needs of the future. Organizational collaboration through technology may facilitate the collection of knowledge from multiple layers and employees within an organization while promoting stakeholder buy-in within the strategic planning process (Bolisani & Bratinu, 2017). Bryson et al. (2018) advised that while current strategic planning efforts are limited to a specific group or team, collaborative efforts to engage organizational members are noted to improve the strategic planning process through the collection of varying ideas and forecasts. In conjunction with the functional definition of strategic planning, collaborative technology such as conferencing programs, social media, and crowdsourcing may enhance the volume of diverse ideas to help forecast both the needs and future objectives of an organization. Although the collaboration and communication of agency ideas may facilitate the planning process, the ideas may only represent a specific paradigm if the collaboration efforts do not include a diverse source of information (Pope, 2004). Collaborative technological platforms, such as social media and crowdsourcing networks, have the potential to bring a diverse range of stakeholders to the table, facilitating a more productive conversation, (Buehring & Liedtka, 2018), while promoting open strategic planning (OSP), grounded in transparency, collective inclusiveness, and information technology (Amrollahi & Rowlands, 2017).

Future Research Directions

The concept of strategic planning has transitioned from a rigid, procedural act to a function of collaborative engagements. With this transition, collaboration has changed from face-to-face discussions to the discourse between physically distant agents facilitated through technological advances in computers and digital communications. As with the case of forecasting the future based upon what is both known and unknown, modern advancements in technology present both welcomed solutions and theoretical questions. The novel concepts of social media and crowdsourcing provide both solutions to existing problems and a future capacity predicated only through additional research.

As the collaborative basis of strategic planning shifted from a limited team-centric involvement to vast social and organizational networks, existing social networking technologies, such as social media, were embraced to facilitate communication within distant and diverse populations (Hautz, 2017). The utilization of social media as an environment for the transfer of ideas has supplemented the legacy forms of personal communication such as telephones and text messaging (Wirtz, Daiser, & Mermann, 2018). Social media has been widely accepted across many sectors for the purposes of strategic planning, yet much work remains in identifying how the characteristics and efficiency of bilateral digital discourse differ dependent upon sector, industry, and technological platform (Hautz, 2017).

In addition to social media, crowdsourcing has emerged as a positive tool to increase collaboration amongst stakeholders working within a strategic planning function. Although research about crowdsourcing and open strategic planning has exponentially increased over the past decade, it remains very much in its infancy. Ghezzi, Gabelloni, Martini, and Natalicchio (2018) have begun exploring how to best leverage the crowd and similar attributes of open strategic planning based upon the Input-Process-Output (IPO) framework. Within this framework, Ghezzi et al. (2018) posited that future research should focus on the structure of problems and questions presented to the potential solvers. As problems and request for ideas may be innately complex, research is needed on how to dissect problems and requests to promote the most efficient work of the agents of whom information is being requested (Ghezzi et al., 2018). If the request for information or problem is not framed to reduce ambiguity, the utility of the returning information may not be compatible with the objectives of developing the strategic plan. In conjunction

with developing the proper framework of requests, additional research is needed on establishing the motivational and beneficial factors of both those seeking information and those providing information (Ghezzi et al., 2018). For crowdsourcing to yield the most productive information, it may be imperative for the facilitators of the strategic planning process to understand what would motivate the greatest number of agents to provide the maximum amount of information. Better understanding citizen engagement, motivation, and encouraging organization management to embrace the diverse ideas received from stakeholders will be critical to unlocking the wisdom of the crowd (Ghezzi et al., 2018; Jordan, Yusuf, Mayer, & Mahar 2016). The failure to include stakeholder ideas may promulgate a lack of buy-in and a sense of non-inclusiveness which may hamper stakeholder interest and public-sector utility.

As crowdsourcing may provide an organization with an overload of information irrelevant to the objective of strategic planning, cost-effective and resource-sensitive measures should be developed to adequately evaluate and sort through the information to determine the qualities of utility and validity. Understanding how people, organizations, information, and technology interrelate is imperative to the effective use of crowdsourcing in strategic planning (Zhao & Zhu, 2014). As the dynamics of a societal culture may be proportional to the level of technological innovation, further research into the integration of crowdsourcing instruments, such as wikis, social media, podcasts, and blogs, is needed to maximize the informational return of crowdsourcing. (Zhao & Zhu, 2014).

As the definition of strategic planning is ever evolving, the collaborative efforts to retrieve information for the planning process changes as well. Continuous research into social media and crowdsourcing platforms is needed to keep up with societal changes as well as to adapt to the changes in technological platforms that may be utilized to retrieve information from a vast and diverse population.

CONCLUSION

Strategic planning has grown from a military strategy to a private sector tool, and finally to a critical public sector innovation. Much of the reason for this public sector growth has been the parallel growth of technology and the changing nature of government over the last quarter century. At a time when public service delivery is increasingly complex and devolved, the need for efficient and effective public sector strategic planning is perhaps greater than it ever has been. Fortunately, the growth of strategic planning has been met, and in many cases exceeded by the vast technological developments of recent years. These advances provide innumerable possibilities for increasing efficiency, capacity, service quality, transparency, and participation if they are utilized correctly (Bryson, Berry, & Yang, 2010).

As Abels (1989) states, strategic planning can be invaluable to a public organization as a tool to gain consensus and determine goals; however, in order for this to happen the organization must “be meticulous in the design of the planning methodology with safeguards integrated into the process that will ensure planning continuation during organization crises or when planning enthusiasm wanes” (p. 295). Technology can do this. It can alter the nature of public service delivery as advances in the internet and the use of social media have begun to show. While the literature has yet to catch up to these advances, the potential is there for strategic planners, but in order to maximize this potential while limiting risks, strategic planners must proceed in a deliberative and cautious manner (Magro, 2012). Technology has and is still changing the nature of public service, and strategic planning must reflect and account for it (Bryson, Berry, & Yang, 2010).

KEY TERMS AND DEFINITIONS

Collaboration: Being an active member of a group working toward a common goal.

Crowdsourcing: Using technology to engage and collect citizen input; leveraging the ‘wisdom of the crowd’.

Networks: Increasingly digital, networks allow the sharing of resources and collaboration of stakeholders.

New Public Management: The government paradigm that advocated running government like a business, with emphasis on efficiency.

Social Media: Websites and applications that allow users to create and share content within a social network.

Strategic Management: The overarching management process of determining how to achieve strategic planning goals.

Strategic Planning: A collaborative approach to organizational planning consisting of concepts and tools that align the present state of an organization with the future's goals and objectives.

5

Viability of the Sustainable Development Ecosystem

Jay Hays

Independent Researcher, Brisbane, Australia

Hayo Reinders

King Mongkut's University of Technology Thonburi, Thailand

1. INTRODUCTION

Sustainable Development (SD) concerns bearable and sufficient economic and social progress and growth—initiatives and strategies designed to enhance the quality of life of a community's citizens or, at the minimum, stabilizing or securing the current state whilst not overtaxing the environment. SD is founded on key principles of sustainability as well as assumptions about society, economics, and the environment—basically about our nature, existence, and “how things work”. As commonly understood, Sustainable Development is development that meets today's demands without compromising the survival of tomorrow (Kates et al., 2016). Thus, Sustainable Development should also be concerned about environmental protection and regeneration, reducing degradation and depletion, finding sustainable alternatives, and restoring what has been spoilt or overexploited. As lofty and “macro” as all this may sound, SD may also be applied at the “micro” level, at the organisational, departmental, or even team level.

At a global level, SD may attempt to address issues of equality, fair distribution, and access, such as championed by the United Nations Global Compact and its 17 sustainable development goals. A prime example is education: a community whose citizens have little chance of becoming educated has slight chance of long-term viability¹ beyond bare subsistence. Individuals lacking skills and knowledge cannot, generally, better their personal circumstances nor can they contribute productively to community welfare.² But whilst the ideals and aspirations of SD are laudable, if not presumed necessary, are they really possible?

This article pursues the question: *how viable is Sustainable Development?* The question might be framed alternatively as, “Is Sustainable Development sustainable?” To interrogate and explicate this question, the authors present an ecosystem model of Sustainable Development, with “ecosystem” defined for this purpose as the complex of interdependent animate and inanimate constituents of a given, or “bounded” community and their interaction, which, over time, reveals established patterns (Hays, 2010a; Hays, 2010b). By interdependence we mean continuing relationships of influence amongst elements that might be understood as cycles of cause and effect (or stimulus and response). This applies to the elements within the system (the bounded part) as well as with its external environment.

Organisations and institutions may be thought of as ecosystems as well, bounded entities inextricably tied to various stakeholders, vying for resources, and in malleable and evolving relationships with their environment.³ To understand an organization as ecosystem is to fathom its richness, complexity, and dynamism—the see it and its relationships as a complete and functioning system. Conceived thusly, an organization is both separate from its environment (bounded), yet inseparable from its larger system and web of relationships (interconnected).

DOI: 10.4018/978-1-7998-3473-1.ch058

An ecosystem is inextricably tied to its environment, implying a dependency and continuous exchange. Under normal circumstances, all of these mutual influences promote a dynamic balance in the ecosystem. Things stay pretty much as they are unless disrupted by some unexpected, uncommon, or extreme event (Hays, 2013). In fact, and as we will show in portrayal of the SD ecosystem, knowing the elements in the system and the character of their relationships helps us make sense of the system's dynamic behaviour, and is what allows us to predict the system's behaviour under various circumstances. Such is the power of the map: an intervention at a particular point is going to have reasonably predictable outcomes.

We usually think of ecosystems as being impacted by external events, such as a community might be affected by a devastating forest fire. It is also the case, however, that ecosystems may have within them—perhaps unwitting or undetected—the seed, or *potential*, for spontaneous transformation triggered by some random stimulus. This emergent property might be destructive or may confer some attribute that will ensure the system's survival, an adaptive quality or resilience suited to shifts in the environment, for example, a threat or opportunity it presents (Walker et al., 2004).

Building on these ideas of Complex Adaptive Systems and the authors' respective and ongoing collaborative research spanning several years into various aspects of sustainability⁴, the authors have developed and present here for the first time a dynamic model of SD as an ecosystem, identifying the key features or variables in the system and their interrelationships. Whilst the approach is novel so far as we know with respect to SD, it is defensible in this case for at least two reasons: such models have been proven to be very instructive in other complex domains⁵, and SD generally focuses its attention at the community or regional level—ecosystems⁶. Positive results may be predicted from systemic interventions because understanding of the features and relationships within the ecosystem allows efforts to be applied to the points of greatest leverage, as has been pointed out in numerous studies⁷.

One hypothesis arising from this fact is that SD initiatives that address their interventions on the target community or region *as a complex adaptive ecosystem*⁸ will be more successful in the long run than initiatives that focus on a particular problem or issue, such as water security or vaccination programs. The same holds true for organisations and institutions, as has been researched with respect to organizational change and development.⁹ This is due, in part, to leverage and synergy amongst efforts made possible through *true-to-life* system mapping and deep understanding of behaviour causality, complemented by deliberately disregarding interventions, that well-intentioned providers might be misled to, based on a more superficial and reactive understanding of symptoms and assumed problem causes (Hays, under review).

The case of a sustainable communities project underway in rural Kenya is briefly described in the article as an example of an ecosystems approach to SD. The case qualifies as an ecosystems approach as it involves a multipronged set of interrelated sustainable initiatives addressing a given community as a Complex Adaptive System. Initiative streams cover: power (particularly directed toward lighting and refrigeration); water security; sanitation, hygiene, and medical care; education and skills-building; agriculture and livestock; industry and commerce; and includes a *train-the-trainer* concept that will enable the progress made and lessons learned from the program to extend to neighbouring communities.

The sustainable communities project is also an example of circular economy (Geissdoerfer et al., 2017; Sauvè, 2016) as resource acquisition, production, use, and reuse are contained and exploited, and profit reinvested into and benefitting the sustainable system and its citizens rather than being funneled into the amassing hands of a few or siphoned off to elements outside of the bounded system. Whilst it is too early to claim success, sustainable communities has the hallmarks of a SD program that might succeed—genuinely make a difference at the local and, quite possibly, regional level.

An important feature of the sustainable communities program is its conscious adoption of and adherence to proven principles of sustainability¹⁰ that can be designed into systemic SD solutions. These

principles and how they apply in the SD ecosystem model are outlined further on in this chapter. As just one example, albeit a prime one, the principle:

*Strive to become self-sustaining and self-sufficient (lessen dependence on external support and funding).
Build internal capacity through learning.*

serves as a reminder that external funding in terms of “charity” (giving a man a fish) is both reinforcing and self-defeating (and the dynamics can be mapped showing the predictable consequences). On the other hand, if the man can become productively educated and acquire useful skills, then he needs no charity and becomes self-sufficient (teaching a man to fish). Of course, it may be the case that an individual (or community) is not immediately or easily converted from a passive, dependent existence to a more proactive, independent, and self-reliant one, a complex phenomenon whose persistent behaviour can also be mapped. Comprising a blend of experience, confidence, knowledge, skill, opportunity, values, expectations, and motives, it is easy to see the scale of impediments to becoming self-sufficient. At the same time, these attributes all need to be addressed in order to achieve sustainable change, and this is an objective of the project in Kenya.

This kind of thinking—attempting to understand dynamic causality in complex behaviour—underpins Causal Loop Diagrams and, indeed, the authors submit, is essential to understanding why some Sustainable Development initiatives succeed and others fail. Our objectives are to increase the success rate.

2. PRINCIPLES OF AND CRITICAL SUCCESS FACTORS FOR SUSTAINABILITY

In this section we identify five Critical Success Factors (CSFs) over which we have some measure of control and 13 related operating principles (OPs). These CSFs and OPs derive from experience with attempts to implement sustainability programs,¹¹ and reference to extant literature, including published research on the closely-related phenomenon of organisational transformation.

Critical Success Factors¹²

Leadership

It is practically a given that leadership be included as a CSF for sustainability programs, as it is widely assumed that change cannot happen without strong leadership.¹³ But, here, we refer not merely to guidance, support, direction, and inspiration provided by traditional authority figures. We emphasise the leadership inherent or potential in the ecosystem that emerges and is developed through activity, experience, and opportunity. This is not positional leadership, but a distributed, shared, and shifting leadership (Sweeney et al., 2019) that steps up when, where, and how needed. If the system does not have its own inherent or developing leadership, it will fail to thrive.¹⁴ Thus, leadership succession and development are essential for sustainable operations.

Emergence

Emergence is a quality of Complex Adaptive Systems whereby a new feature of the system comes about as a result of interactions amongst the system’s elements (Jagustović et al., 2019).¹⁵ There would be

many interactions in the sustainability ecosystem, with various balancing, propelling, moderating, and reducing influences between and amongst elements. Emergence can be a good thing, and may even be essential to long-term survival. In a human social system, emergence can include most anything, from leadership, through ideas and methods, to relationships—all of which may lead to opportunities. Rules, rigid expectations, or restriction may stifle or repress emergence such as one might see in a resolute bureaucracy. On the other hand, flexibility allows emergence to happen and preparedness enables capitalising upon opportunities (Dahlberg, 2015).

Framework

Despite need for flexibility, a framework within which individuals can work and learn is important. For example, what is important to achieve should be clear, consistent, and consensual. How goals are to be pursued should also be understood and complementary strategies followed. While individuals and groups in an ecosystem may have different goals, approaches, and perspectives allowing for emergence, (if complementary) their unified efforts should be related to sustainability—both achieving and embodying sustainability. This is why we propose operating principles and guidelines rather than stipulations, aiming to instill a set of values and aspirations that provide unifying and beneficent purpose, direction, and ways of being and working.

Culture

By culture, we mean shared values, common interests, and complementary behaviours amongst the group.¹⁶ Common behaviours are the result of and further instill ways of doing, being, and working that come to be expected from members of the group and, presumably, productively serve the group.¹⁷ Here, rules, norms, customs, traditions, language, symbols, and communication patterns all apply (Chen, 2016). To achieve long-term sustainability, a culture of continuous learning and development must be cultivated (Beyerlein et al., 2017). As Hays et al. (revise and resubmit) have stated,

An organisational culture of sustainability engages most members continually and is rewarding to do so. It orients new members and embraces them into the doing and being of sustainability. Obvious facets of such culture-building include the codified vision, values, and priorities for sustainability and Corporate Social Responsibility, with every member ... having relevant and respective accountabilities (np).

Relationships

An operational ecological-ecosystem view of the world adheres (and is subject to) the interconnected “web of life” notion (Capra, 1996; Capra, 2007). It is probably the case that little that is complex, enduring, and important can be achieved alone (Solon et al., 2018). There are too many factors impeding progress to get much traction independently. But there is strength in numbers and diversity (Ingegnoli, 2013). Interaction and collaboration with different people and organizations may pose challenges, but confer capabilities and capacities that single-mindedness simply cannot (Hays, under review).

This section presented five Critical Success Factors for viable SD. These are shown in Figure 1 as an interlinked set. The five are not the entire ecosystem, but do collectively comprise a major part, as discussed below. Whilst each factor has its own distinct attributes, they all overlap and interact; they work together to “power” the SD ecosystem. This is the idea of synergy—interaction amongst elements

Figure 1. Five Critical Success Factors for viable Sustainable Development

in a system produces attributes and outcomes unaccounted by the simple sum of the individual parts (Lee and Green, 2015). Without all of these factors, we suggest, SD will fail in the long run. With them, a robust ecosystem may be possible.

The next section enumerates Operating Principles for viable SD. As space precludes elaboration, we do not explain each principle here; but will incorporate them into the discussion of the viable ecosystem model (Causal Loop Diagram) that follows.

Operating Principles

In addition to the Critical Success Factors identified above, the following operating principles added value in the sustainability projects in which we’ve been involved or needed in the ongoing work.

Table 1. List of operating principles

■ Find and build champions.	■ Plan for succession and evolution.
■ Find a meaningful job for everyone.	■ Plan and host multiple events and activities.
■ Have and keep to a learning and research agenda.	■ Empower, decentralise, encourage initiative.
■ Permit energies and resources to flow towards and with good ideas.	■ Interact, collaborate, and build partnerships. Promote diversity.
■ Envisage sustainability as a daily discipline and set of practices—develop mastery.	■ Befriend nature and the environment. Act as concerned citizens within the “web of life”.
■ Build sustainability into the system: codify, educate, embed, and reward sustainability measures (such as durability, adaptability, sufficiency, efficiency).	■ Operate with integrity and ethics. ■ Always think of the bigger picture and the part that each element plays in it. Act in accord with long-term benefit, rather than short-term ease or gain.

3. CAUSAL LOOP DIAGRAM

This section presents a basic Causal Loop Diagram (otherwise known as a relationship or influence diagram) of the Viable Sustainable Development Ecosystem. Belying its complexity, the diagram is portrayed to comprise 11 elements, or concepts, each of which is explained in the sequentially-numbered paragraphs below. Relationship diagrams add value to understanding complex system phenomena in

at least two ways. First is identification and explication of key variables or factors, here referred to as concepts. Second, and more importantly, relationship diagrams trace the direction (if not power) of influence between and amongst system variables.¹⁸ For example, in Figure 2, Commitment and Motivation, Item 5, is shown to be influenced by both Positive Outcomes, Item 10, and Failures, Item 11, albeit in diverging directions. In this case (and as explained below), these affects make sense to the reasoning mind and are clearly established in reinforcement theory.¹⁹ How and why they apply in our model of the viable sustainable development ecosystem is explained below. Beginning to reveal the true complexity of the ecosystem, each concept (items 1-11) is described with respect to the Critical Success Factors and Operating Principles discussed in the previous section.

Figure 2. Basic Causal Loop Diagram of the Viable Sustainable Development Ecosystem

In general, it does not matter where you start in a Causal Loop Diagram as the elements are all connected in some way, sometimes intricately or subtly, the “web of life” idea. But for practical purposes, you have to begin somewhere. In this case, we have labelled SEQ, Knowledge about Sustainability and the Environment, located in the lower left-hand of the diagram, item 1.

Finally, before beginning our “walk around the map”, please remember that this relationship diagram attempts to depict the *viability* of SD. Viability will depend on the virtuous dynamics displayed by the ecosystem, and will be undermined by vicious cycles allowed to enter or permitted to continue operating in it.

1. SEQ—Knowledge about Sustainability and the Environment

To read the relationship diagram, trace the lines of influence connecting elements. Here, you will note that SEQ is connected to Items 2, 3, 4, 10, and 11. The number of connections an element has to other elements indicates its relative importance or prominence in the system. Thus, SEQ is one of the moderately significant elements in our ecosystem, surpassed only by Commitment and Motivation (Item 5), to which we turn shortly.

Implied by SEQ is the collective volume of knowledge, awareness, and appreciation of the members of the ecosystem (community or organization in question) concerning sustainability and the environment—current conditions, understanding of causality, implications for the future, and knowledge with respect to effective strategies and initiatives. This capacity may be developed in a community or orga-

nization in a variety of ways, including committing to a learning and research agenda, allowing energy and resources to flow where they will have likely constructive impact, sponsoring multiple events and activities, and fostering collaborations, partnerships, and diversity. The main Critical Success Factor, here, is building a culture of sustainability.

For now, we see that the sense of urgency and imperative (to act) (Item 2) is fed by SEQ. As SEQ rises (or diminishes) urgency and imperative will rise or fall correspondingly. This is important as urgency and imperative bear on both Resources (Item 4) and Commitment and Motivation (Item 5), and, possibly, to Thought Leaders (Item 3), as well (suggested by the dotted line-arrow. The model would suggest, as is consistent with experience, that initiatives will not initiate or sustain without Resources and Commitment and Motivation.

Also shown as part of SEQ dynamics is that Thought Leaders (Item 3) positively affect Knowledge about Sustainability (Item 1) and vice versa. As one goes up, so does the other. This is a positively reinforcing loop, presumably a virtuous cycle, if we are interested in the viability of sustainable development. Of course, the opposite is also true, if one goes down, the other will reduce as well. Thought leaders include any individual or organisations that fill positions of influence. They could be scientists, business and government leaders, or influential members of society and media personalities. Obviously, the less ambiguous, debatable, or conflicting their messages, the greater the impact of Thought Leaders.

Continuing, we see that Resources (availability) (Item 4) impacts SEQ. Greater Resources would build increasing SEQ through education, training, and public service communications and information campaigns. Resources include funding, time, and people devoted to sustainability and the environment, including those directed toward Corporate Social Responsibility initiatives.

Finally, we see that Positive Outcomes (Item 10), that is “success stories” from sustainability and environmental initiatives, and “bad news”, Failures (Item 11) from efforts both affect SEQ by providing more information about what works and what doesn’t, as well as if effort is even worth the investment. This is reinforcement theory at its best. It would be reasonable to assume that the greater the number and kind of Positive Outcomes and the awareness about them would “fuel” the viable sustainable development ecosystem.

Sense of Urgency and Imperative

Sense of Urgency and Imperative has already been partly discussed in Item 1. Key points are that it is influenced mostly by SEQ (Item 1) and Thought Leaders (Item 3). A building Sense of Urgency and Imperative is driven by threat or fear—dire reports on current conditions or predictions about impending consequence of previous misuse or neglect. Whether or not founded on fact or grounded in reality, perceived threat can drive attention resulting in greater resource allocation (Item 4) and Commitment and Motivation (Item 5) to act, key drivers of mobilisation. Either or both of these effects can lead back to SEQ (Item 1), directly and indirectly, with Thought Leadership (Item 3) also being affected.

Referring to our Operating Principles, those most applicable here are having and keeping to a learning and research agenda, conducting diverse events and activities with a range of stakeholders, encouraging collaborations, partnerships, and diversity, and connecting individuals and units to relevant Thought Leaders. Whilst leadership is key, here, in stimulating a sense of urgency and imperative, a framework for channeling that energy is essential. Also critical is a uniting culture in which members feel shared purpose, commitment, and belief that together they may succeed.

It is important to note that Sense of Urgency and Imperative can diminish in either of two cases, which may or may not be desirable, depending on actual circumstances. In the first case, SEQ is weak, thus

there will be no sense of urgency and imperative. In the second case, SEQ is strong, but the state of the environment is presumed to be healthy or improving. Thus, there is no need for urgency and imperative. Practitioners should remain aware of the differential effects of SEQ.

Thought Leaders

As discussed above, Thought Leaders (in this instance) are individuals or organisations known as authorities regarding sustainability and the environment whose opinions are sought and influential. Since they can influence and, possibly, inspire others through word and deed, they impact Knowledge about Sustainability and the Environment (Item 1), Sense of Urgency and Imperative (Item 2), and Commitment and Motivation (Item 5). Thought Leaders emerge through the accumulation of relevant knowledge (SEQ (Item 1)) and, though not shown, becoming recognised or being promoted up the ranks in academic, business, and government organizations as with other specialists and experts. Given this, the most applicable Operating Principles include providing meaningful jobs, finding and building champions, instilling succession planning, and developing mastery. Allowing and encouraging relationships is a Critical Success Factor.

Thought Leaders may emerge or be urged into influential platforms given the sway of Urgency and Imperative (Item 2) and / or the stimulus of Commitment and Motivation (Item 5) inherent in the ecosystem, as indicated by the dotted line-arrows.

Resources

Resource availability and distribution in our ecosystem largely come about due to Sense of Urgency (Item 2) and Commitment and Motivation (Item 5), both elements serving as drivers pursuing resources and relinquishing them. This does not indicate where resources come from, but it is essential in a viable model of sustainability that the system, itself, has the capacity and capability of generating and managing its own resources. This assumption also explains the links toward SEQ (Item 1) and to the Skills, Knowledge, Reflection subsystem (Items 7, 8, and 9) in the upper-right hand side of the diagram. Whilst not immediately apparent, we have to assume that knowledge and skill acquired through education and experience will bear on the system's ability to generate resources and effectively mediate how they are used. Thus, meaningful jobs, empowering and decentralising, mastery, and integrity and ethics in conduct of business are all key Operating Principles. What is needed is to develop a culture of self-reliance.

Commitment and Motivation

Commitment and Motivation occupies a central position in our ecosystem, with no fewer than six connections (relationships with other elements). We have explained the influence of Sense of Urgency and Imperative (Item 2), Thought Leaders (Item 3), and Resources (Item 4) already. Another key factor with respect to Resources and its influence on Commitment and Motivation is that commitment and motivation are likely to diminish under conditions of sparse resources: effort may feel unrewarding to individuals, required for sustained endeavor, and chance of success perceived by members as slim, also a factor undermining optimism and determination.

This notwithstanding, when the element of Commitment and Motivation is high, Action (Item 6) is more likely, some of which results in Positive Outcomes (Item 10). As Positive Outcomes increase, Commitment and Motivation is also likely to go up, forming a positively reinforcing loop.

On the other hand, as Failures (Item 11) increase, Commitment and Motivation is bound to suffer—a negative effect, as indicated by the (-) at the tip of the line-arrow leading from Failures. To stem this affect, supportive leadership is required (not shown in the link), as is learning from failure, also not directly shown, but suggested by the link to the Skills, Knowledge, Reflection subsystem.

Given the nature of and dynamics surrounding Commitment and Motivation, leadership is a Critical Success Factor—keeping individuals inspired, directed toward constructive activity, and rewarded for effort and initiative. An empowering culture of productivity with encouragement to learn from failure is also essential. A framework for action is a third CSF, here, incorporating Operating Principles including ongoing learning and research, allowing energy and resources to flow where they may do the best good and to seed fledgling initiatives, and providing multiple and diverse events and activities that might spawn ideas and give birth to new initiatives.

Action

It could be argued that any action is better than doing nothing. Whilst there is no doubt some truth to that, some actions are better than others, and wisdom may be called for in dictating what course of action to follow or when the chosen course needs to be shifted or halted. Though wisdom does not appear in our model, it is suggested by the link from Reflection (Item 9) to Action, and may be considered an essential quality of our ecosystem leadership CSF, along with the Operating Principles Integrity and Ethics, Big Picture / Greater Good / and Long-Term Thinking, and Befriending Nature and the Environment.

Not just any action, but skillful and appropriate action is also required. In our relationship diagram, this is shown as the function of the Skills, Knowledge, and Reflection subsystem, and funneled largely through Reflection (Item 9). The greater and more effective the Action, the greater the production of Positive Outcomes (Item 10), and the fewer Failures (Item 11).

Not shown, but certainly worth consideration, is that *action reflected upon* will produce learning (Moon, 2013) and contribute to greater Positive Outcomes, so the function and value of Reflection as part of the learning dynamics of our Viable Sustainable Development Ecosystem should not be underestimated.

Skills

There is a wide range of skills required to build and sustain a viable ecosystem. Since, SEQ (Item 1) is concerned with knowledge about sustainability and the environment, we focus here on managerial, technical, and social skills required to solve problems, make decisions and operationalize plans and implement solutions. We also include the skills required for continuous learning, training, professional development, mentoring, and coaching, for these are needed if a system is going to successfully adapt to and evolve within a changing environment. These skills are important to bring into the ecosystem but also to develop amongst existing members, thus one CSF is a culture of learning, along with the particular Operating Principles Learning and Research Agenda, Meaningful Jobs, Succession and Evolution, Empower and Decentralise, and Mastery.

Skills is part of the Skills, Knowledge, Reflection Subsystem, and our maps shows these three elements operating in concert to drive ecosystem learning and performance. Whilst not shown, Reflection (Item 9), itself, is a skill and disposition that can and should be fostered. There may need to be an ecosystem (organizational) framework for reflection and learning and a culture that encourages them.

Knowledge

This is not so much SEQ (Item 1), but knowledge about the business and its environment—the kinds of things every organization needs to know to continue learning. This is knowledge needed to solve problems and to make informed decisions, and to keep the ecosystem evolving to meet changing conditions. Reflection (Item 9) is shown to feed knowledge in our model, so, again, plays a vital role.

Whilst thorough coverage of organizational knowledge is far beyond the scope of our current discussion, it should be clear that a culture of learning and knowledge is critical to the ecosystem's survival, supported by leadership and frameworks that allow emergence and exploitation of new ways of thinking, new ideas, new relationships, and new ways of working. More than anything, this suggests an organic, flexible, and responsive type of organisation unencumbered by bureaucracy and rigid controls.²⁰

Reflection

Reflection and its contribution to learning and effectiveness are extensively covered in the literature, and, as educators, we can hardly conceive of a learning or professional development process or activity that excludes it. In any circumstance, we believe reflection to play an integral role in the learning, adaptation, and evolution of the Viable Sustainable Development Ecosystem. In our map, Reflection is shown to have positive relationships with Skills (Item 7), Knowledge (Item 8), Action (Item 6), Positive Outcomes (Item 10), and, a negative relationship with Failures (Item 11).

Again, Leadership and a Culture that promotes reflection, especially with teammates, colleagues, and partners, will more often than not build learning and resilience and contribute to positive change (Hays and Reinders, 2018). Corresponding Operating Principles include: Building-in Sustainability (in this case, reflective practice), keeping to an evolving Learning and Research Agenda, holding Multiple Events and Activities, Empowering the workforce and Decentralising authority, Mastery, and fostering Collaborations, Partnerships, and Diversity.

Positive Outcomes

Desired, positive outcomes are rewarding in their attainment, but also important in that achievement provides fuel for continued effort. The gratification feeds Commitment and Motivation (Item 5), contributes to amassing knowledge (SEQ (Item 1)), and provides substance for Reflection (Item 9). Given the power and value of Positive Outcomes, an organization should celebrate wins as much as possible, focusing not solely on the specified outcomes, per se, but also efforts, techniques, and processes that lead to achievement.

Failures

Whilst doubtful that anyone really likes to fail, failure plays a significant role in the Viable Sustainable Development Ecosystem. We see that Action (Item 6) and Reflection (Item 9) flow into Failures, and Failures (Item 11) influence Commitment and Motivation (Item 5) and SEQ (Item 1). As Actions (Item 6) increase, that is, initiatives and responses to environmental threats and measures taken to improve sustainability rise, Failures are likely to increase, as would Positive Outcomes (Item 10), other things being equal. This is merely a matter of numbers. What would reduce Failures, other than chance, would be improving ecosystem knowledge and skill as funneled through Reflection (Item 9). Failures would

also diminish if Actions (Item 6) were to decrease, but this is probably not desirable. Both action and failures are likely to reduce in environments averse to risk and where failures are punished, though this dynamic is not shown on the map.

Failures can be productive when learning from failure is exploited. This is indicated on our map by the influence line pointing to SEQ—Knowledge about Sustainability and the Environment (Item 1), in a case of “what works and what doesn’t”. So, we want not to reduce failures, per se, but to reduce unnecessary ones and to optimize *productive failures*²¹.

This discussion on failures highlights the importance of allowing them to occur, perhaps even celebrating them, at least those that shed light on problems and their solutions, and reveal assumptions that may be impeding effective solutions. Likewise, it emphasizes the importance of learning in a viable ecosystem. Thus, again we see our Critical Success Factors at work, especially and obviously Leadership, Culture, and Framework. Some of the Operating Principles evident are Building-in Sustainability, Learning and Research, Mastery, Multiple Events and Activities, and Collaborations, Partnerships, and Diversity

In sum, the Causal Loop Diagram of the Viable Sustainable Development Ecosystem identifies elements and their interrelationships considered to be important for understanding the dynamics of SD. It portrays the ecosystem as comprised of various relationships that at least partly explain why a SD program might succeed or fail. To the degree that elements included and the lines and directions of influence amongst them are correct and complete, the CLD can be predictive—what will happen if we increase Thought Leadership (Item 3)? What are the likely consequences of driving Action (Item 6) in the absence of a learning subsystem (Items 7, 8, and 9)?

No map of a complex adaptive ecosystem can be completely accurate. This one is simple, with fewer than a dozen elements. No doubt readers might add or interchange elements or find competing or alternative dynamic relationships. But the CLD offered here provides a glimpse into the phenomenon of SD not previously depicted in this way. Considering the elements and their dynamic relationships as intricately and mutually linked may suggest new possibilities, initiatives, and strategies permitting practitioners and policymakers to better understand impediments, shift emphasis, and gain more value from available resources.

DIRECTIONS FOR FUTURE RESEARCH

This chapter outlines five Critical Success Factors and a baker’s dozen Operating Principles for viable Sustainable Development, and 11 elements comprising the Sustainable Development Ecosystem. Whilst each of these arise from the authors’ experience, observations, and insights, the factors, principles, and elements are individually and collectively open to challenge and deserve further investigation. They may be incomplete or insufficiently understood, and based on limited exposure to the breadth and depth of Sustainable Development initiatives worldwide. By nature, Complex Adaptive Systems are difficult to define and the dynamic interdependencies amongst elements may be speculated but hard to prove. This said, we have done the best we can to envisage Sustainable Development as a complex ecosystem and explain the logic of the many and variable relationships amongst its elements.

We trust researchers and practitioners can draw from and build upon our work. How our CSFs, OPs, and the CLD account for successes and failures in past and ongoing Sustainable Development projects would make for interesting and useful studies. Additionally, particular interventions and investigations might consider, for example:

- The merit of conceiving Sustainable Development as an ecosystem, and/or community-as-ecosystem.
- Alternate ecosystem views of Sustainable Development.
- If not ecosystem / Complex Adaptive System conceptualisation, what makes Sustainable Development viable?
- The veracity of the Causal Loop Diagram presented, and its elements and their relationships.
- Applicability of the five Critical Success Factors, and a more-thorough understanding of their character and implications.
- Utility of the Sustainability Operating Principles and their translation in specific contexts and initiatives.
- Our hypothesis that Sustainable Development initiatives will be more successful in the long term to the extent that they deal with problems as Complex Adaptive Systems.
- And, finally, what is the contribution of the Sustainable Development Ecosystem to addressing the UN's Sustainable Development Goals?

SUMMARY AND CONCLUDING REMARKS

This chapter introduces the idea of SD as an ecosystem and explains how and why it may be fruitful to conceive of SD in this way. The case is made through use of a detailed Causal Loop Diagram (the model or “map” at Figure 2) that provides key features of the SD ecosystem—the main elements and their interdependencies. Critical analysis, discussion of the model, and explanation of the dynamics involved suggest the circumstances under which SD will likely be sustainable and when it will predictably fail. Armed with such knowledge, policymakers and practitioners can make more informed decisions about where to intervene in a *community-as-ecosystem* (Murphy, 2018), that is, how best to invest the limited resources available.

Working with the Causal Loop Diagram and moving toward the idea of a Viable Sustainable Development Ecosystem, the authors came to what—in retrospect—might be an obvious observation. To be sustainable, Sustainable Development must be wise, for all that implies.

A wise system exhibits numerous virtues, but fundamentally is concerned with greater good and long-term flourishing, forsaking short-term ease or gains, knowing and honouring itself and its interdependence with nature and its environment, and consciously learning to be increasingly effective and resilient (Hays, 2010a; Hays, 2010b). This, it seems to us, is the challenge and solution for SD. What are the principles of sustainability that will guide us toward a healthy future, including both internal operations and interactions with our environment? How can we best build in sustainability to SD initiatives and programs? What essential conditions must we create to be sustainable? What are the attributes of mastery in sustainability, and how do we best develop them?

We cannot provide a complete answer, yet, and, possibly, never will be able to. But our explication of the Viable Sustainable Development Ecosystem does reveal Critical Success Factors and Operating Principles that give clues as to what we can do. The most conspicuous CSFs are leadership, culture, framework, and relationships, but emergence should not be overlooked. Emergence may provide the greatest possibilities for a viable SD ecosystem, given healthy and supportive leadership, culture, and framework for operating. One example would be what positive learning can come from failures.

We also identified and provided examples of sustainable Operating Principles. Those most often apparent are learning and research; building sustainability in to all operations and facets of the business; providing many and diverse opportunities for ideas to emerge, including promoting interactions,

collaborations, and partnerships of all kinds; and fostering flexible and organic structures and ways of working wherein individuals feel unimpeded by hierarchy or bureaucracy.

Our wise SD ecosystem is comprised of people who individually aspire to mastery—they demonstrate unwavering discipline in thought and deed, ever vigilant to what opportunities exist in themselves and in their communities to become more sustainable and focussed on making those improvements. They are courageous and driven to act, but always address the first question: is this the right and best thing to do for all stakeholders all things considered? As masters, they do not lord over anyone, but are always willing to step up to calls for leadership, taking a stand on issues that matter, speaking for those whose voices have been unheard, and reminding us all of the vital commitments we have made (or must make) to create a sustainable world for all inhabitants.

If the understandings arising from the Critical Success Factors and Operating Principles we have identified and the concepts and dynamic relationships we have elucidated here are incorporated into the planning, implementation, and evaluation of SD initiatives, they are surely to be at least more sustainable than would otherwise be the case.

KEY TERMS AND DEFINITIONS

Complex Adaptive System: A system—such as a community or organization—having many elements that continually interact and influence one another in complex and, sometimes, unfathomable ways. Though striving for stability and security, the interactions produce behavior and structure not before seen (emergence and self-organisation).

Critical Success Factors: CSFs are factors or conditions that must be present in order for an initiative to succeed or a given process or desired condition to sustain. For example, sustainability implies that a system must have within it the capacity to generate its own resources (rather than be wholly dependent on external sources).

Ecosystem: A bounded system of living and interdependent entities in dynamic interaction with their environment, influencing and being influenced by their environment. Here, a socioecological system such as a community or organization.

Relationship Diagram: Otherwise known as Causal Loop or Influence Diagrams, these are “maps” or depictions of the salient elements in a Complex Adaptive System or ecosystem, and their relationships to one another shown as lines (directions) of influence.

Sustainability: Thriving into the future. Necessary for survival, sustainability implies cautious use of resources, including curtailing waste and other threats to the environment, production that does not exceed what can be replenished, and cultivation of products, services and lifestyles that enrich rather than exploit.

ENDNOTES

¹ Viability is a key concept in the real world and in this article, as indicated by the title. For us, viability has to do with capability to survive or, better, to thrive *independently*, that is, without undue and continuing external support—to succeed on its own. A viable proposal or intervention would be practical, realistic, achievable, and suited for purpose given existing circumstances, and robust and resilient in the face of challenging conditions. In many ways, viable means sustainable. To be viable, then, Sustainable Development must be able to be implemented or operationalised in such a way that its purpose is met—it achieves what it intends to—and continues to succeed into the future.

² As with viability, community is also an integral concept here. We are using community to designate a particular locality within which people live and interact, a social system comprising all of the things people need to survive, as well as resources they may share or compete for. It is likely that people living in a designated locality have common interests, values, culture, and so on, but increasingly the population will be diverse. No doubt, however, they would be united in desire to survive, if not flourish, though may have vastly different understandings of how that might be attained and sustained. For our purposes and with respect to Sustainable Development, inhabitants of a given community would need to establish mutually productive and beneficial behaviours for an ambitious SD intervention to succeed. This implies that a critical mass of a community’s members needs to embrace and live by the objectives of a given development or other change project for it to be achieved. For all this means, it is probably the case that a Sustainable Development project of any scope may have to concern itself with *community* development addressed through concerted communication, education, and culture change initiatives.

Corporate Social Responsibility, Irresponsibility, and Citizenship

Duane Windsor

Rice University, USA

INTRODUCTION

This article explains three related conceptions: Corporate social responsibility (CSR), corporate social irresponsibility (CSIIR), and corporate citizenship (CC). The traditional word “corporate” is not restrictive to large and publicly traded corporations. “Corporate” can have the broader meaning of all “business,” including small and medium sized enterprises and B (i.e., benefit) corporations. The three conceptions involve significantly different approaches for answering the overarching question of the appropriate relationship between “business and society.” A prominent journal, *Business & Society*, founded in 1960 and sponsored in recent decades by the International Association for Business and Society, reflects this field title. The relationship sometimes has the labels “businesses and societies” (pluralizing the term) or “social issues in management.” The latter is the name of a division of the Academy of Management (founded in 1936). These three labels are essentially synonymous.

The emphasis in each conception is on defining legal and ethical responsibilities of business enterprises and business executives toward society and environment. The “responsibility” approach emphasizes a broad and multidimensional understanding of how businesses can contribute positively to societies. This approach can be contrasted with a narrowly economic conception of profit that disregards negative externalities of business decisions. The “irresponsibility” approach emphasizes strict compliance with legal and ethical standards for conducting business. It distinguishes between “harm” and “altruism” to emphasize that reducing harm caused by businesses is considerably more important empirically than inducing those businesses to practice altruism. The “citizenship” approach invokes “a political metaphor” emphasizing voluntary choices of businesses and executives as distinct from externally imposed responsibilities.

The article has four objectives. One objective is to lay out the basics of the three conceptions responsibility, irresponsibility, and citizenship, as developed to date in extant literature. A second aim is to contrast economic, ethical, and strategic perspectives bearing on these three conceptions. A third aim is to connect the three conceptions to corporate social performance (CSP), corporate governance, and the stakeholder theory of the firm. A final objective is to propose solutions, recommendations, and future research directions for addressing key problems in the field.

Research Methods

This article uses two research methods. The first and dominant method is a literature review. This review has three key dimensions. The review provides a summary of published work on the set of three related topics of responsibility, irresponsibility, and citizenship. The reviewer provides a logical structuring of that work. The review includes a critique of the strengths and weaknesses of the extant literature. The

DOI: 10.4018/978-1-7998-3473-1.ch059

critique clears a path for proposed solutions, recommendations, future research directions. This review is not systematic in the sense of identifying and discussing every published work. The review seeks to provide the reader with a guide to the extant literature in a way that will facilitate further exploration into key issues. The reader can begin with the reference and additional reading items the author selected to reflect the range of those key issues. The secondary method is use of selected cases to illustrate instances and applications.

Limitations of the Study

There are three basic limitations. First, the works and cases reflect the views of the author. The literature review is explicitly selective. Second, the review includes some empirical studies. However the review of empirical work is selective rather than a systematic survey. The survey is not a meta-analytical study of findings. The literature review focuses on conceptual and theoretical work. Third, the linkage of responsibility, irresponsibility, and citizenship to other topics is quite limited. The focus in linkage is on performance, governance, and stakeholder concepts.

BACKGROUND

CSR is the traditional conception against which one can compare and contrast irresponsibility and citizenship conceptions (Windsor, 2006, 2013). The modern idea of CSR emerged in the 20th century as a response to the perceived negative effects of unregulated laissez-faire markets and Social Darwinism philosophy (London, 1904) in the 19th century. This response reflected both Marxist criticism of industrialization and, in the United States, the Progressive criticism (about 1890-1920) of the Gilded Age (about 1865 to 1900). Andrew Carnegie (1889) published an essay on wealth, which advocated responsibility of the wealthy for philanthropy. The piece later appeared as an essay on the gospel of wealth in *The Pall Mall Magazine* (London), and then in Carnegie's (1901) collection of essays. Carnegie's view reflected Christian principles and voluntary philanthropy. His "gospel" carries forward in today's *The Giving Pledge* the Gates and Warren Buffett started in 2010. The adherents pledge to donate at least half of their net worth.

Progressivism in the United States was a political movement drawing on both liberal and populist trends. Over time this movement targeted urban political machines and promoted women's suffrage, antitrust legislation, governmental efficiency, and prohibition. The movement established various new regulatory agencies, such as the Food and Drug Agency and the Federal Reserve System. Theodore Roosevelt (Republican) and Woodrow Wilson (Democrat) were prominent Progressive Era presidents. Progressivism moved beyond voluntary philanthropy to impose various new regulations on business (Wood, 1986). The 1920s were a resurgence of political conservatism. The 1930s Great Depression and World War II regenerated business interest in social contribution. This business interest continued until the end of the 1960s.

Friedman (1970), who won a Nobel Prize in economics, started an intellectual counter-revolution. He criticized CSR on two grounds. First, CSR is managerial theft masquerading as corporate altruism, but in reality reflecting managerial preferences adverse to shareowners' financial interests. Second, CSR is a drift toward socialism and an interference with government's proper sphere.

Businesses should obey laws and customary business ethics, while lobbying governments for benefits. The Friedman criticism was less a return to 19th century laissez-faire economics and more a reemphasis

on profit seeking (Jensen, 2002). Profit seeking received increased emphasis from the widespread embrace of agency theory in economics and finance. Agency theory dominated American business schools educating generations of MBA students. Agency emphasizes the fiduciary duty of executives to generate profits for shareowners of publicly traded corporations. It focuses corporate governance on the problem of monitoring and incentivizing executives to that purpose.

This economics-based movement against CSR resulted in efforts by proCSR academics and executives to define a persuasive intellectual basis. CSR promotes business ethics, corporate philanthropy, and environmental sustainability. This promotion includes specific policy goals, such as reducing poverty and child labor, ensuring widespread access to health care, or promoting increasing wealth in developing countries. This proCSR response over time gave rise to CSR, CSiR, and CC approaches (Carroll, 1999; Davis, 1973).

RESPONSIBILITY, IRRESPONSIBILITY, AND CITIZENSHIP

Ethical and Economic Views of Responsibility

The basic contest in CSR literature and practice has been between an ethical view and an economic view (Kitzmueller & Shimshack, 2012). The development of ethical CSR theory is strongly associated with Carroll (1991, 1999, 2000). This theory posits that moral managers behave differently than do amoral or immoral managers (Carroll, 2000). The economic view reduces business to a profit orientation. A more recent critique of CSR argues that psychological microfoundations are ill-explored (Aguinis & Glavas, 2012). A different viewpoint argues that governments, activists, and media should regulate businesses in place of voluntary self-regulation by businesses (Karnani, 2011).

Figure 1. Carroll's pyramid of four corporate social responsibilities

Carroll (1991) depicted a set of four responsibilities in the form of a pyramid, as Figure 1 shows. This pyramid can be isosceles (meaning at least two equal sides) or equilateral (meaning three equal sides), or a step pyramid. The essential feature is that each layer (or dimension) from the foundation to the apex becomes smaller in relative size. In Figures 1, 2, and 3, the dimensions are color-coded as green for economic, red for legal, blue for ethical, and brown for philanthropic. Economic performance and legal compliance are mandatory, ethical responsibility is expected, and philanthropy is desirable (Carroll, 1991).

Surveys of business executives (Aupperle, Carroll, & Hatfield, 1985) suggest that they may tend to assign 10 (or 100%) in roughly the same order as the pyramid at 4: 3: 2: 1 (or 40%: 30%: 20%: 10%) for economic, legal, ethical, and philanthropic. As Figure 1 shows, Kang and Wood (1995) proposed a revision of Carroll's pyramid. This revision moved ethical responsibility to the foundation, succeeded by legal responsibility and then economic responsibility. Subsequently, Meynhardt and Gomez (2019) explained how to generate variations on the four-dimensioned model.

Later, Pedersen (2010) surveyed more than 1,000 international firm managers from various sectors and countries. The highest responsibility this author reported was environmental—reflecting a likely shift over time in understanding of the specific content of responsibility. The next responsibilities concerned product quality, then employees, and then community and society. Shareowner value or wealth received the lowest mention frequency. Baden (2016) argues that this recent information reinforces the idea of inverting the pyramid in accord with the revision Kang and Wood (1995) proposed, as Figure 1 depicts. According to Baden, the highest frequency mentions correspond to ethical responsibility.

In combination with empirical data on the views of business executives, Carroll's pyramid is implicitly also a causal model of how the four responsibility elements promote firm financial performance. Economic responsibility is broader than simply profit, which is a resultant reflecting success at providing goods and services to consumers and jobs and compensation to employees. Legal compliance and ethical conduct help to promote strategic competitive advantage and economic performance. The whole pyramid is infused with an assumption of moral management, such that the four dimensions are strictly separated, but interact for a moral manager. An amoral or immoral manager in contrast separates profit out of economic responsibility and pays no attention to the other three dimensions.

An economic (or theory of the firm) perspective defines CSR quite narrowly as “actions that appear to further some social good, beyond the interests of the firm and that which is required by law” (McWilliams & Siegel, 2001, p. 117). This perspective follows Friedman (1970). While McWilliams and Siegel's definition includes legal compliance, these authors ignore customary business ethics. They separate CSR actions into two kinds. One kind concerns CSR actions a stakeholder, who is prepared to pay the firm for those actions, demands. For example, customers may be willing to pay higher prices for environmentally friendly goods. This kind of CSR action is simply just another business decision. The other kind concerns CSR actions the management supports, for which no stakeholder is prepared to pay. This kind matches Friedman's criticism of CSR. A problem with the theory of the firm perspective is that it focuses on a one-period decision: The firm either makes money (or at least breaks even) or loses money; the former situation is simply a business decision, while the latter situation is the one Friedman criticizes. This one-period focus is nonstrategic. Strategically, “the interests of the firm” may involve multiple-period planning, stakeholder satisfaction, and building reputational capital. Strategically, a firm might need to lose some money in the present, in order to hold competitive position, or make more money in future time periods. A purely economic perspective can be criticized as being a straitjacket (Brooks, 2010).

Figure 2. Conceptions of corporate social responsibility choices

CSR theorists adapted to the controversy over the status of corporate philanthropy, and more broadly altruism, by excluding it from the formal framework. The adaptation restricted responsibilities to economic, legal, and ethical. Carroll had regarded philanthropy as effectively discretionary. Figure 2 shows the depiction of a proposed solution the author adapted from Schwartz and Carroll (2003). These authors use a three-dimensional Venn space model, in which space is a set of related elements—some of which can overlap. A business chooses the particular combination of the three dimensions by shrinking or increasing each Venn space. The business can change that combination over time. In Figure 2, the three spaces are equal in size. Thus the ordering of the three dimensions has no significance—the reader can simply spin the spaces. Once the sizes are varied, the largest space should presumably be at the top. To generate the “Creating Shared Value” Venn space depiction (Shared Value Initiative, n.d.), in Schwartz and Carroll’s framework it is necessary to substitute business opportunities for economic choices, social needs for legal choices, and corporate assets for ethical choices. The intersection of the three Venn spaces is “shared value.” A Venn space is simply the set of all logically related ideas, such as the set of economic choices or the set constituting the ethical perspective. Where Venn spaces overlap, the sets share elements. Figure 2 compares Schwartz and Carroll’s depiction to a different three-dimensional depiction the author adapted from Windsor (2006). Windsor suggested three alternative approaches or perspectives: Ethical, economic, and citizenship. Figure 2 explicitly places the ethical perspective at the top, on the argument that ethics dominates and informs both citizenship and economic perspectives.

Given the economic criticism of CSR, considerable literature has focused on formulating a “business case” for responsibility including environmental sustainability and on finding empirical evidence supporting that business case. A business case justifies a decision on the basis of improved profitability

or improved reputation or improved strategic positioning and competitive advantage (Carroll & Shabana, 2010; Tonello, 2011). A business case is instrumental in nature: A particular action will result in a desired improvement in financial performance. The business case is in effect a win-win solution: The business gains and social welfare either improves or at least remains constant. The requirement is that the business gain does not occur at the expense of social welfare.

Controlling Irresponsibility

Two problems with the conventional CSR approach are that it tends to merge with demands for corporate philanthropy and altruism and those demands tend to expand. There is in effect a virtually unlimited agenda for costly CSR initiatives. This problem ameliorates, if much of the agenda comprises profitable opportunities. Corporate altruism is subject to the criticism Friedman (1970) articulated. A business is profit-oriented, not social-benefit-oriented (Strine, 2012). Recently, attention has shifted to the causes and impacts of corporate irresponsibility, in order to identify effective controls on misconduct.

Figure 3. A broader definition of CSR (adapted from Windsor, 2013)

Figure 3 adapts an approach Windsor (2013) proposed. The vertical axis depicts the interaction between the market economy and the government. The market economy rewards a business for economic performance (goods and services, and jobs and compensation) and stakeholders' satisfaction with profits (rising with degree of monopoly power). The government provides public goods (defined as goods and services the market economy will not provide, but desired by taxpayers) and regulations in the forms of criminal laws, civil laws, and public policies. Capitalism is a mixed economy of private and governmental actors providing goods and services and regulations. The box at the center of Figure 3 is a Venn

space that in effect measures the size of the aggregate social welfare which is generated by the mixed economy. For purposes of the depiction, the aggregate social welfare is a momentary equilibrium which is measured at the immediate time period. This aggregate social welfare moves up and down dynamically with the mixed economy's functioning. The horizontal axis thus shows negative or positive changes from the momentary equilibrium due to nonmarket actions by a business. Legal or ethical violations impose harm on at least one person and thus reduce social welfare. The next subsection discusses citizenship contributions.

Citizenship and Political Corporate Social Responsibility

The CC interpretation (Hemphill, 2004) involves two “conflicting interpretations”: (1) An instrumental interpretation views corporate philanthropy as a strategy for building reputational capital, while (2) an ideal interpretation restates ethical responsibility and reflects expanding needs for corporate philanthropy (Windsor, 2006). This latter interpretation seeks to increase corporate accountability (Waddock, 2004).

Reducing CSR to corporate responsibility by removing the word “social” effectively leaves the definition of responsibility to the discretion of business managers. In this simplification, managers can choose among the economic approach, the stakeholder satisfaction approach, the strategic approach, or even traditional CSR.

CC should increase social welfare in some way. The market economy may dynamically adjust to offset the cost of citizenship or the firm may elect to absorb the cost directly in the form of reduced profits. Citizenship costs are likely to be reasonably limited (Strine, 2012).

In 2010 (*Citizens United v. Federal Election Commission*) the United States Supreme Court held (5 to 4) that the First Amendment's free speech clause prohibits restrictions on independent expenditures on public communications by business corporations, nonprofit organizations, labor unions, and associations. Examples of the latter are National Rifle Association and Sierra Club. Underpinning the majority opinion is a view of the business corporation as an artificial person, which thereby enjoys certain citizenship rights.

Related to the idea of CC is political CSR. Switzerland-based scholars Andreas Scherer and Guido Palazzo and colleagues in Europe (Scherer, Rasche, Palazzo, & Spicer, 2016; Scherer & Smid, 2000) pioneered this perspective. The essence of political CSR is that businesses have a duty to promote democracy internally to the organization and in society externally to the organization. This duty exists whether the host country for a multinational enterprise is developed or developing. Businesses also have a duty to provide public goods in instances in which the government lacks capability to do so. This duty is most pronounced in developing countries. The political CSR approach advocates a very strong form of CC which is designed to improve social conditions, including democracy.

Strategic Philanthropy and Shared Value Creation

Michael E. Porter and Mark R. Kramer developed new conceptions of strategic philanthropy (Porter & Kramer, 2002) and shared value creation (Porter & Kramer, 2011). Strategic philanthropy argues that charitable giving by businesses should serve some strategic purpose, rather than being in effect a random selection reflecting managerial preferences. In other words, the business should get some form of return on philanthropy, and that return can be focused: Higher return is preferable to lower return. Shared value creation argues that businesses can be profitable by solving social needs, and such profitability can be focused: Higher profit is preferable to lower return, not to mention to loss. These conceptions of strate-

gic philanthropy and shared value creation are the core of Porter and Kramer's view of CSR (Porter & Kramer, 2006). Shared value generates at the intersection of business opportunities, social needs, and corporate assets. Shared Value Initiative (n.d.) provides a depiction of three intersecting Venn spaces (see Figure 2). It may be feasible to measure shared value creation (Porter, Hills, Pfitzer, Patscheke, & Hawkins, 2012).

A study of corporate philanthropy in relationship to specific performance dimensions found that worse performers are likely to make larger charitable contributions than do better performers for environmental issues and product safety. They do not do so for employee relations (Chen, Patten, & Roberts, 2008). The study uses pooled data (1998-2000) for a sample of 384 United States companies. These authors interpret the findings as suggesting that corporate philanthropy occurs for legitimization, rather than as CSR. Worse performers attempt to offset bad reputation through charitable donations.

There has been criticism of the shared value creation approach (Crane, Palazzo, Spence, & Matten, 2014). In effect, the approach narrows CSR to a win-win condition only: Both the business and the society must gain. This condition corresponds to the McWilliams and Siegel (2001) model, in which either CSR is profitable or some stakeholder is prepared to compensate the business for a CSR initiative. Other conditions may occur for CSR. The reader should envision a simple two-by-two matrix with the business on one face and society on the other side. The options in addition to win-win are win-lose (business wins and society loses) and lose-win (business loses and society wins). The win-lose condition corresponds to CSiR: Business gains by imposing harms on society, such as uncompensated negative externalities. The lose-win condition may correspond to regulation of that CSiR: Society changes legal and ethical standards to control such negative externalities or other harms. Lose-lose (both business and society suffer) is undesirable for society. CSR and CSiR theorizing highlights a broader conception of how business and society interact. Win-win is definitely desirable, but this condition is not the exclusive context for CSR and CSiR.

SOLUTIONS AND RECOMMENDATIONS

Moral vs. Nonmoral Managers and Management Education

CSR rests on moral management: Moral executives do not engage in CSiR. Whether moral executives have a duty to engage in citizenship is more problematic. A situation at DuPont illustrates the problem of CSiR by nonmoral executives (Shapira & Zingales, 2017a, 2017b). As these authors report, DuPont used a toxic chemical in a West Virginia plant to manufacture Teflon®. DuPont settled litigation for \$670 million. Analyzing the documents which were made available through discovery in the lawsuit, these authors conclude that it was *ex ante* rational for DuPont to pollute in spite of the final costs to the firm and the harms imposed on society. The education of managers in business schools and the incentives for managerial decision making must emphasize CSR and citizenship over CSiR. The demand for responsible managers may exceed the supply of such managers, and the management education process may bear part of the responsibility (Windsor, 2018). It may be more important to move managers away from CSiR, than further toward citizenship behaviors. In Russia, working for Alcoa, William O'Rourke (Graham, 2012) set an explicit policy of not submitting to corruption, and reported various instances of attempted extortion by local officials. This exemplar is in direct contrast to the DuPont calculus.

If managers report significant support for CSR and against CSiR, as the author illustrated above in this article (Aupperle et al., 1985; Pedersen, 2010), a conceptual and empirical question remains as to

why those managers underinvest in CSR and citizenship (Hafenbraedl & Waeger, 2018). If managers exploit legal “loopholes” to minimize tax payments, such exploitation might be simply fiduciary duty or CSiR or absence of citizenship (Aharony & Geva, 2003). A theoretical standard is necessary for assessing which explanation is valid.

Defining and Measuring Corporate Social Performance

CSP focuses on the identification and measurement of the outcomes of business activities. The Triple Bottom Line (TBL or 3BL) performance framework is an instance. In TBL, the outcomes—portrayed as business performance dimensions—are economic (profits), environmental (planet), and society (people). Desirably, all outcomes should be positive (win-win-win). For any one or two positive outcomes, any other dimension or dimensions should be constant (meaning neither a positive nor negative change in outcome). Wood (1991a, 1991b, 2010) published the key work on CSP theory and measurement. Wood linked motives, actions, and outcomes into a coherent theoretical framework.

CSR, CSiR, and Citizenship in Developing Countries

There is a continuing debate concerning whether CSR, CSiR, and CC are universal (or global) conceptions applicable to all countries or should properly vary by country (Logsdon & Wood, 2002). A typical dividing line in this regard is between developed and developing countries (Windsor, 2017). This debate also encompasses cultural variations, which are not necessarily grouped by developed and developing countries. A study of Swiss Re, the large reinsurance company headquartered in Switzerland, explores multiculturalism in a developed country (Sachs, Rühli, & Mitnacht, 2005). A cross-country empirical comparison of France and the United States found significant differences concerning CC in two developed countries (Maignan & Ferrell, 2000). Variation in national institutions may be important in CSP (Ioannou & Serafeim, 2012).

Multinational Enterprises

A special topic concerns the responsibilities of multinational enterprises (MNEs) operating across national boundaries (Bondy, Moon, & Matten, 2012). Several variations occur in this special topic: Home country and host country are both developed; home country is developed and host country is developing; home country is developing and host country is developed; home country and host country are both developing. Further distinctions exist among emerging countries and transitional countries. An emerging country (e.g., Brazil, China, and India) is a developing country that has achieved industrialized economic growth and increasing international economic presence. A transitional country (e.g., Poland, Kazakhstan, and Russia) is a developing or emerging country that was previously under formal communist rule and has transitioned into formal noncommunist rule. China is an emerging country, but remains under formal communist rule.

Corporate Sustainability and Environmental Sustainability

Pedersen’s (2010) results suggest a shift in managerial concerns toward environmental sustainability. It seems reasonable to link the other managerial concerns Pedersen reported to the related notion of corporate sustainability. Political CSR arguably intersects with environmental sustainability, in the sense

that businesses must take responsibility for influencing government policy in the direction of protecting the natural environment (Lyon et al., 2018). An empirical study finds that liberal-oriented businesses are more likely to support environmental sustainability than are conservative-oriented businesses (Di Giuli & Kostovetsky, 2014). It is desirable that businesses see environmental investments as win-win opportunities (Eichholtz, Kok, & Quigley, 2010).

FUTURE RESEARCH DIRECTIONS

The futures of CSR, CSiR, and CC are difficult to predict (Lee, 2008; Windsor, 2001), given the theoretical disputes and the relatively weak empirical evidence. This evidence suggests that responsible behavior associates positively with financial performance, while irresponsible behavior associates negatively with financial performance. The DuPont litigation tends to undermine the latter. Four research directions are critically important: Integrated theory, empirical evidence, international standards, and cross-country conditions.

Integrated Theory of Business Responsibilities

The developmental history of the social responsibility literature involves a set of controversies. It seems understandable that a contest exists over such an important topic. One main cleavage is between economic and ethical perspectives. The economic viewpoint emphasizes dynamic markets and reasonable liberty for business action. This viewpoint tends to view CSR as voluntary altruism. The ethical viewpoint emphasizes responsibilities of moral managers. Research should address whether the relationship between these two viewpoints is necessarily competitive or may be complementary on some basis. Another cleavage is among economic, ethical, and strategic approaches. A strategic viewpoint emphasizes long term outcomes and the importance of reputation with stakeholders. A third cleavage is between responsibility and citizenship language. Responsibility tends to suggest duty or obligation; citizenship tends to suggest liberty and right to participate in lobbying.

There is some opportunity to integrate responsibility and citizenship theorizing with CSP, corporate governance, and the stakeholder theory of the firm. CSP is about outcomes, governance is about who controls decision rights in a business and why, and businesses are dependent to some degree on stakeholder support. Stakeholders include customers, employees, investors, and managers at the core of a business and additional interests, such as communities, governments, media, and suppliers. Positive and negative externalities of business actions generate stakeholders of a firm. There are increasing linkages to corporate political strategy for lobbying governments and international institutions.

Empirical Investigation of the CSR-CFP Relationship

A major emphasis in CSR literature has been on discovering empirically whether a positive relationship occurs between CSR and corporate financial performance (CFP). A meta-analysis of empirical studies concluded a small positive relationship existed (Orlitzky, Schmidt, & Rynes, 2003). An earlier survey of the problem had concluded that research was highly incomparable and did not yield definite findings, whether positive or negative (Griffin & Mahon, 1997). The purpose of such empirical research is to demonstrate to managers that CSR is at least modestly profitable. One empirical study suggests a curvilinear relationship in which both CSiR and CSR behaviors can be profitable, and that the profit advantage of

CSR over CSiR may be sufficiently small that managers can choose to be bad and profitable (Barnett & Salomon, 2012). However, unless the profit advantage of either CSR or CSiR over the alternative is marked, the choice of strategic approach is basically up to management discretion. The reader might consider a momentary equilibrium in which the profit advantage is constant for any two firms. If one firm selects a CSR strategy and the other firm selects a CSiR strategy, both firms might gain about the same profit advantage: Under this condition, the selection is up to the executives. The DuPont case may have been markedly more tilted toward CSiR being profitable and CSR being unprofitable. A moral manager will tolerate at least small loss in preference to doing wrong and imposing harm on others.

A meta-analysis of empirical findings involves the difficulties of assessing ex ante bias of researchers and the “file drawer problem.” In this problem some research may be rejected and thus suppressed during the journal review process. It is not possible to measure these two difficulties rigorously. In general, antiCSR scholars may expect nonprofitable findings, while proCSR scholars may expect profitable findings concerning the CSR-CFP relationship. Possibility a large number of studies reflecting both views may help. Scholars conducting meta-analysis studies can issue calls for unpublished research to address the file drawer problem (Rost & Ehrmann, 2017; Wang, Dou, & Jia, 2016).

Evolution of International Corporate Social Responsibility and Corporate Social Irresponsibility Standards

One approach to influencing managerial behavior is the development of internationally agreed standards for CSR, antiCSiR, and citizenship (Windsor, 2004). Such standards and corresponding international agreements have been evolving over the years. One example is the United States Foreign Corrupt Practices Act (FCPA) of 1977. In combination with a similar Swedish anticorruption statute (1978) and anticorruption activists, FCPA helped to result in near-universal adoption of the United Nations Convention against Corruption (2005). O’Rourke’s (Graham, 2012) experiences in Russia reflect this emerging anticorruption consensus. The United Nations Global Compact includes nine principles concerning human rights, labor rights, and environmental protection and a tenth anticorruption principle. The International Standards Organization has adopted ISO 26000 CSR guidance and ISO 37001 guidance on anticorruption systems. Various global and regional environmental protection agreements exist, including the 2015 Paris Agreement on limiting greenhouse-gas-emissions. The Global Reporting Initiative provides standards, evolving over time, concerning corporate reporting about topics, such as climate change, corruption control, and human rights. The United Nations is working on a human rights framework including the role of business.

Variation in Cross-Country Conditions

An emerging debate concerns whether CSR is universal and, if so, set by developed countries without much respect for the interests and views of developing countries. CSR emerged in developed countries, and reflects particularly views in North America and Western Europe. These views are not automatically consistent. There is increasing conversation in developing, emerging, and transitional countries concerning whether the extant understanding of CSR fits their conditions and needs. Countries in Africa, Latin America, and East Asia may have quite different institutions and traditions shaping views of MNEs and CSR standards. Continuing scholarship into cross-country variation is highly desirable.

CONCLUSION

The relationship between business and society is a topic of fundamental and continuing importance. This circumstance generates both interest and disagreement. This article examines CSR, CSiR, and CC. The examination places the three conceptions in relationship to one another; and to relevant topics such as CSP, corporate governance, and the stakeholder theory of the firm. Responsibility of businesses to societies remains a highly contested topic for scholars and practitioners with proCSR and antiCSR positions. The relationship among economic, ethical, and strategic perspectives lacks resolution. Empirical evidence on the relationship between CSR and CFP is perhaps weakly positive in favor of CSR and antiCSiR over the long term. However, any range between mildly negative and mildly positive leaves decisions to management judgment.

The article has explained the background to CSR and the developmental history of the conception. The article has provided detailed information on the economic, ethical, and strategic perspectives, and on the emergence of alternative conceptions of CSiR, CC and political CSR, and strategic philanthropy and shared value creation.

The key recommendations in this article concern management education, CSP definition and measurement, developing countries, MNEs, and the emerging shift in responsibility concerns toward business sustainability and environmental sustainability. The key research directions identified concern how to develop an integrated theory of business responsibility, continued empirical investigation of the relationship between CSR and CFP, and the evolution and effectiveness of international standards for CSR, antiCSiR, and citizenship. There should be continued investigation of variations in cross-country conditions, particularly between developed and developing countries.

KEY TERMS AND DEFINITIONS

Corporate Citizenship (CC): A political metaphor in which the corporation has constitutionally an artificial citizenship which can be interpreted either as liberty to pursue strategic philanthropy and lobbying of governments in place of external requirements and expectations or as an equivalent to corporate social responsibility in different words.

Corporate Social Irresponsibility (CSiR): The theory that violation of legal or ethical standards by a business is irresponsible misconduct, typically resulting in illegitimate and avoidable harm to others for business profit.

Corporate Social Performance (CSP): Desirably positive economic, social, and environmental impacts or outcomes of corporate activities. Such impacts or outcomes can be negative or neutral.

Corporate Social Responsibility (CSR): The theory that businesses have broad responsibility to society for positive corporate social performance (CSP) and avoidance of corporate social irresponsibility (CSiR).

Economic Responsibility: The condition that businesses cannot practice extralegal responsibilities if they are losing money. Economic responsibility is also the expectation that business profits are a resultant of positive economic performance in the form of goods and services for consumers, and jobs and compensation for employees.

Environmental Responsibility: The duty or obligation of a business or a business executive to promote environmental sustainability.

Ethical Responsibility: The duty or obligation of a business or a business executive to comply with ethical standards and expectations.

Legal Responsibility: The duty or obligation of a business or a business executive to comply with criminal and civil laws and public policies.

Philanthropic Responsibility: An expectation that profitable businesses should make voluntary charitable contributions in support of home country communities in which they operate.

Triple Bottom Line Performance (TBL or 3BL): A framework within which organizations attempt to maximize jointly three bottom lines, which are typically characterized as people (social welfare), planet (environmental sustainability), and profits (business performance).

INTRODUCTION

Corporate Social Responsibility (CSR) – both as a concept and an adopted practice – is ubiquitous and in widespread use by international, national and local corporations, and supporters, skeptics, and critics alike. It is also a growing area of concern and practice for businesses, in particular in relation to challenges such as poverty, sustainable development goals, climate change, environmental issues, and a range of diverse ethical issues. More recently the issue of corporate social irresponsibility has emerged and will be tackled here briefly in the next section (Section 1) and in the section on solutions and recommendations (section 4).

This chapter reviews the literature and the main problems related to corporate social responsibility, to identify the most important current challenges and their relevance to management and business information systems. Sustainability and social responsibility tools - such as the Global Compact, Global Reporting Initiative (GRI), SA8000 standards and ISO 26000 standards - have drawn our attention.

In the first section, we review the literature on the CSR concept and its context. In the second section, the focus is on the discussion of CSR issues. In the third section, the discussion focuses on the problem of communication, internal management of knowledge, stakeholder participation and management of information and knowledge systems. Finally, the last section emphasizes the main challenge for the near future.

BACKGROUND

The Concept of CSR

It is important to talk about Corporate Social Responsibility (CSR), this is a fundamental concept for the most part of corporate decisions (Cochran, 2007), when we look at the relations between them and society. Its definition has been developing, with many proposals from academics, commentators, consultants, companies, civil society and governmental organizations.

DOI: 10.4018/978-1-7998-3473-1.ch060

When investigating different ways of defining CSR, Banerjee (2008) concludes that, in relation to companies, in all we find three aspects: they must generate wealth, attending to environmental and social issues; should behave ethically, revealing high integrity and transparency, and they must engage with the community in which they carry out their activities, improve their well-being and support them through philanthropy or other means at their disposal.

“Firms are stepping up their environmental and social performance because investors are asking for it” (Dyck, Lins, Roth, Wagner, 2019). Studies such as that of Hou (2019) conclude that “socially responsible firms can achieve financial results superior to those of firms which do not pursue CSR initiatives”. Other authors consider firms are “being socially responsible”, they will have a tendency to experience minimized shareholder wealth and lower profits, which restricts the socially responsible investments (Lin, Law, Ho, Sambasivan, 2019).

For the outside observer, CSR is an opportunity for the company to self-regulate, to monitor its activities, and to respect the spirit of the law, ethical standards, and international norms, with positive impacts on the environment, consumers, and all other interested parties (Torrecchia, 2013).

Since the beginning of the first decade of the twenty-first century a growing number of companies have published SR reports or social responsibility reports. The writing and publication of CSR reports end up defining the company’s responsibility to the stakeholders, highlighting its values and building a relationship of trust.

Tanimoto (2015) reinforces accuracy, credibility and comparability of information as, if each company provides information according to its own criteria, it will not be possible to compare information between companies and justifies the role of the Global Reporting Initiative (GRI) to ensure the validation and certification of SR reports and adds yet another challenge: national governments should control the existence of such reports, believing that they can increase value for business and confidence levels to stakeholders.

Miguel, Jorge, and Candas (2017), in favor of social responsibility, consider that companies with better CSR performance have fewer funding constraints and suggest that for those corporations CSR may be considered as a lever for their reputation in the market and for their differentiation from competition, which is favorable not just for attracting institutional investors but also for fostering existing relationships with the main credit institutions.

Large companies, under pressure from representative entities of society, join the social responsibility (SR) in various ways, responding to various social demands (Torres, 2005). Because of this, some take ownership of social discourse and are an influence for other organizations by adopting or reproducing the same discourses and practices that are being disclosed as good and positive practices in social and environmental areas.

The existence of several stock indexes, whose listed companies have to meet a series of demanding conditions in areas such as environment and social governance prove that financial markets value these matters. In the United States, the Dow Jones Sustainability Index emerged in 1999 and the FTSE4GOOD in the United Kingdom emerged in 2001.

In 1999, the UN Secretary-General launched an initiative, which, in terms of SR, sought to make a commitment among the entities of all countries, challenging companies to adhere to and implement within their action the principles and values of human rights, working conditions, the environment and anti-corruption actions. It is the Global Compact which aims at companies to consider in their strategies and operations 10 principles (Global Compact Network Portugal, 2011).

Among the existing codes, principles, and norms in the SR domain, we summarize some initiatives:

- SA8000 Standard: First specific standard related to SR, produced and promoted by Social Accountability, 1997 (SAI, 2017).
- The AAA000 series of AccountAbility standards introduced in 1999 by the Institute of Social and Ethical Accountability (ISEA, 2017)
- ISO 26000: International Standards for Business, Government and Society standard finalized in 2010 (ISO, 2017).

We can attribute one contribution that the private sector has made with the founding in 1992 of the World Business Council for Sustainable Development (WBCSD, 2017), the world's leading organization in the business approach to sustainable development.

Being the main driver of CSR in Europe and aiming to strengthen the European strategy for corporate responsibility, the European Commission launched in 2001 the Green Paper "Promoting a European Framework for Corporate Social Responsibility", presenting CSR as a concept in which integrate social and environmental concerns into their operations and their interaction with stakeholders voluntarily.

One question remains in CSR, when the adoption of a widely construed conception of responsibility, how can be conceptualized corporate social irresponsibility? Without entering too much debate, in the present chapter and approach, social irresponsibility for corporations can be defined as the increase of environmental costs, external costs for society, communities and stakeholders. It can include even shareholder as a subcategory of group who bear costs when the management of the organization is responsible for negligence or fraud or any behavior that can be considered non-righteous. The irresponsibility goes beyond mistakes, simple ones. It includes big mistakes and any behavior that is considered clearly as irresponsible by the main standards of ethics and business ethics.

APPROACHES AND MANAGEMENT OF CSR

At this point, we will address how companies organize and manage CSR. In summary, we highlight the following three approaches to social responsibility:

Carroll's Pyramid, with Enormous Formative Influence on CSR

Carroll (1979) argues that the SR fully addresses all the obligations a company has towards society and must incorporate the economic, legal, ethical and discretionary categories of business performance. These categories are not mutually exclusive, but ultimately suggest their role in the evolution of their importance. Carroll also identifies the social issues to which companies may have to respond, underlining the importance of managing their non-commercial agendas, anticipating here somehow the management of stakeholders, by highlighting the possibilities of being able to give a business answer to the questions of those agendas, expecting a strategic approach to CSR. Later, Schwartz and Carroll (2003) considered only the economic, ethical and legal domains in CSR, using the Venn model, abdicating the pyramid model with 4 categories.

The Stakeholder Theory, Designed for The Business Strategy but Adopted in CSR

Popularized by Freeman (1984), at the heart of the issue lies because corporate management should not be limited to the interests of shareholders/owners - but also to the interests of other stakeholders. Although Freeman has already stated that stakeholder management is not unique to CSR, many companies have adopted this model as a way of thinking and managing their responsibilities, believing in involvement, collaboration and communication with the parties concerned.

The Triple Bottom Line (TBL) approach, which provides a way of integrating economic, social and environmental responsibility

The triple bottom line approach, also known by the three Ps - profit, people and planet -, is another way of approaching CSR. Developed by John Elkington (1997) from the UK consultancy firm SustainAbility, this model is perfect for understanding sustainability, since it contains the economic, environmental and social aspects that must holistically interact to be sustainable.

The shared value creation approach, which highlights the business case in CSR.

Porter and Kramer (2011) suggest the “shared value” in business, an approach some companies have adopted in relation to CSR. These authors recommend to companies the design of products and the choice of markets according to the needs of societies; the redefinition of productivity in the value chain, to reduce negative impacts and maximize positive ones.

In order to adopt CSR practices derived from sustainable development principles, it is necessary to take into account the different dimensions in which a company can act. Usually, we consider three dimensions: social, economic and environmental.

Following Santos et al. (2005, p. 31), the social dimension integrates the actions oriented to the management of the human element that composes its social matrix (internal component) and actions oriented to the surrounding community (external component). The economic dimension of companies relates to three types of partners: customers, suppliers and investors or shareholders. “Corporate environmental responsibility involves the integration of environmental issues into strategic management, giving them due importance, along with economic and social issues” (Santos et al., 2005).

We can broadly define CSR as responsible practices that are expected to create benefits for society as well as for its stakeholders (Lantos, 2001 and Porter and Kramer, 2006). Since short-term obligations prevent indiscriminate investments in this value creation, CSR is a long-term investment in the company’s future competitiveness (Porter and Kramer, 2006). Corporations can take advantage of their competitors (Orlitzky, Siegel and Waldman, 2011). If companies invest in CSR with the same structures that are at the basis of their most important choices, they will realize that SR can go beyond costs, obligations or charitable works - which may be opportunity, innovation and competitive advantage (Porter and Kramer, 2006). And while there is a growing appreciation of sustainable development, Porter and Kramer (2006: 154) argue that it is rare for companies to know how to do social action in an effective and sustainable way, noting that “by linking corporate philanthropy to their sector and its strategy, the company can, more than other donors, improve the performance of beneficiaries, further enhancing social value. “

In a complementary perspective, there are those who defend CSR, which is closely linked to risk management, which is already an integral part of the organizational strategies of modern companies. It should be noted that corporate scandals or environmental accidents can cause considerable damage to a company that may have worked hard to build a good reputation. In order to mitigate and anticipate these types of incidents, SR can be integrated into the organizational culture (Meulbroek, 2002).

The CSR strategy emerged as a concept to incorporate goals into future planning that enables enterprise performance management to integrate CSR approaches (Werther and Chandler, 2006). However, these corporate strategies have been the subject of several criticisms, including their lack of ambition, their tendency to be in a market-related department, public relations and human resources, that they are generalist, may vary from region to region and negative consequences may be obtained, albeit unintentional (Werther and Chandler, 2006).

In response to such criticisms, there are already companies that seek greater involvement with their stakeholders, ie NGOs, employee representatives and stakeholders, and incorporate their CSR activities more broadly into business strategy (Galbreath, 2006). This presupposes that the company has clearly defined the direction of its CSR approaches and its links to its strategic objectives, which implies that the needs of the stakeholders are analyzed in the short and long term, sought to be evaluated and incorporated them in business objectives. Thus, the CSR strategy is expected to deliver beneficial outcomes for all parties, including the community, through positive economic, environmental and social impacts (Katamba et al 2012).

“Companies give priority to CSR activities that are directly related to maintaining business and achieving economic results. CSR disclosure practices of SMEs and large companies do not differ significantly. However, larger companies disclose more information on Environment and Society. Companies who are closer to consumers disclose more information on Customers, Community and Society. The act of assuring a CSR report drives system improvements and extended CSR disclosure” (Dias, Rodrigues, Craig, Neves, 2019).

MANAGEMENT OF STAKEHOLDERS AND COMMUNICATION OF SR

In 2007, Freeman, Harrison, and Wicks came to give importance to the management of stakeholders in order to create value, aiming at the sustainability of organizations. Through positive long-term relationships, it is possible to identify win-win opportunities for all parties serving the company, stakeholders and society (Goodstein and Wicks, 2007; Svendsen, 1998).

Due to the proximity to the core of the company, we can distinguish two large groups of stakeholders (García, 2012: 89): internal (eg shareholders, partners, managers, employees - directly linked to the company and its organization) and external (e.g. (eg, customers, suppliers and subcontractors, authorities, pressure groups, local communities, regulators and employers' associations, trade unions, and professionals, NGOs, competitors, consumers - interest groups not directly linked to the organization). But this is just one of many classifications.

Lambin (2000: 336) defines competitive advantage as the set of characteristics or attributes of a company that put it in a position superior to its most immediate competitors. Today's companies seek competitive advantages and to build them can follow several paths: traditional vision, resource-based vision and vision based on superior stakeholder management (Rocha, 2010).

In the traditional view, five steps compose the strategic management process (Certo and Peter, 2005):

1. Analysis of the environment (internal and external);
2. Establishment of the guideline of the organization;
3. Strategy formulation;
4. Implementation of the strategy
5. Strategic control.

In the resource-based view, an organization is a set of resources that integrate themselves into categories (Goldschmidt, 2010):

1. Financial resources;
2. Physical resources (factory, equipment, facilities, and access to raw materials);
3. Human resources (encompass skills and training);
4. Knowledge and organizational learning;
5. Organizational resources (formal structure, systems, control, and coordination, culture and reputation).

In the vision based on superior stakeholder management, the road to building competitive advantage is built with an outward look, that is, for customers, competitors, partners, the press and society, looking for new ways of creating and delivering greater value than the competition (Rocha, 2010).

According to Goldschmidt (2010), the principles of sustainability in business, messages emitted by companies to their stakeholders can be related to any of the three items that make up the tripod of sustainability (environmental, economic and social performance). This implies ethical and transparent practices for all types of audiences with whom the company relates. Sustainability can thus present itself as a source of competitive advantage, contributing to this by how its different aspects are linked to the company's value generation model.

In order for the company to contribute to the promotion of sustainable development, it can invest in a stakeholder involvement process.

Calahorro (2008: 36) refers to the need to develop a Relationship Plan for supporting the CSR Strategic Plan, which summarizes six points:

1. Identify and catalog the different groups of stakeholders;
2. Analyze the expectations of each of them;
3. Establish priorities among the different actions that each group seeks;
4. Define programs;
5. Implement the timetable of the different programs;
6. Design a model of communication with different audiences.

After identifying the stakeholders and despite the complexity of the topic, each one should be analyzed individually, with their responsibilities and interests, taking into account the type of relationships they establish with the organization. Transparent corporate governance, transparency, and reporting to company partners and all stakeholders are increasingly important as a way to obtain social licenses for any company to operate, develop long-term activities with sustainability. This transparency implies a sincere, fast and spontaneous communication, close to the stakeholders. All of this is becoming increasingly important in an increasingly competitive world in which we have been overwhelmed by corporate scandals.

Described by McShane and Von Glinow (2003) as the process by which information is transmitted and understood between two or more parties, communication has gained increasing importance in companies, even considering itself strategic. Being essential for the durability of the company's relationship with stakeholders, communication enables the creation of positive associations and reinforcements (Kim and Rader, 2010).

If Corporate Social Responsibility reflects the company's attitude toward the environment and society, we affirm that corporate communication will ensure the company's dialogue with its stakeholders, effectively enabling that responsibility.

We can talk about sustainability communication, when the company uses different channels and languages, adapted to its most varied public, thus informing them of their practices of social responsibility. In this way, the company raises public awareness and stimulates the occurrence of this type of activity (Formentini, 2003: 4), making known what it has done, how and to whom it has done, thus expecting to add value. "When developed with ethics, transparency and a lot of competence, business communication is able to synthesize the company's commitment to society and all its stakeholders, allowing the aggregation of value to the business, which can contribute to a positive public image" (Araújo, 2009 and Bueno, 2003: 118-119), that is, a positive mental perception that the different publics have of an organization and that would have been constructed by the set of messages received by them in all their relations with it. We must not forget that a solid reputation of the company motivates employees, attracts investors, new customers, maintaining current ones, and can even reduce capital costs.

From another perspective, we can also talk about communication for sustainability, from a perspective where learning is shared, for example, promoting education for sustainability, thus broadening the interest and focus to new interests that go beyond the company.

When a company decides that SR incorporates the management of the company and is transversal to all of it, all its actions must be integrated in its policies, so the communication not only should not be left out and must be submitted to SR policies that are seen as authentic by society. And the success of a business communication strategy depends very much on the communication strategy to integrate into the company's overall strategy (Clutterbuck, 2001: 30).

The communication of corporate social responsibility can be defined as the "communication that is designed and distributed by the company itself, about its actions of social responsibility" (Morsing, 2006: 171). to provide true information about the company or brand, integrating business and social operations (Morsing and Schultz, 2006).

In CSR communication is very important, starting with its strategic design and implementation of programs and activities. Sustainability reports, codes of ethics, principles, standards, and content of messages in the most diverse marketing and publicity materials can be considered tools of communication of the social responsibility of an organization.

As can be seen, CSR is communicated through the traditional model of message transmission that implies: who says what, through which channel, with what effect? Communication processes and actions cannot be separated from CSR programs and activities. Being an interactive process, communication implies the existence of dialogue, based on bidirectional and unidirectional communication strategies. There are certain organizational contexts in which information about CSR is only transmitted, and others where the idea is to discuss and negotiate CSR with certain stakeholders. Only with a strategically defined, organized and implemented communication policy, is it possible that the company's SR principles are understood and internalized by its stakeholders.

With respect to the two-way communication Hodggers and Grayson (2002: 260) state that for a stakeholder to be effectively involved, a socially responsible company should have as its principle transparency and the promotion of dialogue with and between stakeholders. a communication channel open in both directions, where all of them feel committed and have the possibility to participate actively in the most diverse policies, assessing the needs of the community, defining and understanding the participation of the company to respond to such needs.

CSR communication faces a particular challenge, which is that more and more companies feel pressured to inform their stakeholders about how they are contributing to society, but on the other hand, different stakeholders can interpret the company's SR communication, unique only as an act of self-promotion (Coombs and Holladay, 2011). And it is also for this reason that companies should seek to ensure that stakeholders' perceptions of SR actions they carry out are in line with their strategic objectives, while maintaining consistency with their image and identity (Formentini, 2003: 4).

SOLUTIONS AND RECOMMENDATIONS

The issue of corporate social responsibility and irresponsibility is complex, as we have tried to highlight in the previous sections. Other authors share the same approach (Herzig and Moon 2013; Rriera and Iborra 2017)

The principles and objectives of CSR should be strategically aligned with other management objectives, being inseparable from it, under its relational culture. Thus, stakeholder management and SR communication will be more facilitated and more effective, and may have positive repercussions on business, the environment, and communities.

One way of further change - and research (see next section) – is to help tackle this issue of irresponsible behavior, misdeeds and opportunism is to deepen our understanding of: (1) what is corporate social irresponsibility; (2) what are its variegated features across cultures and societies; and (3) how social norms and legal rules can regulate or not those unwelcomed attitudes.

Beyond these partial solutions, it is relevant to integrate CSR in a reflection of corporate and management value, decisions and behaviors. This means that CSR has to be integrated in a broader debate and in broader policies that include the fight against corruption and irresponsible behavior.

Finally, it is time to move beyond self-control and to either (1) make it socially accountable or (2) turn it compulsory on some crucial dimensions. Self-regulation is not enough, other tools such as social, political and administrative regulation, including administrative authorities and agencies, have to be mobilized. This is clearly an issue of public debate and public policy.

FUTURE RESEARCH

Although CSR has been the subject of many studies since the 1970s and there is a great deal of literature on the subject, there are still few works that link the sustainable development of the territories. It is desirable to develop studies on social investment policies linked to local business development programs, to what extent companies support the research and development of social investment initiatives, by sharing their knowledge and know-how in actions that promote not only business priorities, but also that maximize benefits for the sustainable development of communities.

Another research that should be associated with that study has to do with the interest and capacity that organizations have to organize themselves in a network and of this benefit to the business and society.

It is necessary to investigate how companies are using the information and communication technologies to communicate SR, and in particular how they use the internet and social networks to interact with stakeholders.

As important as the previous study is the development of impact analysis methodologies for the development of SR actions in the business and in the communities, to better clarify the benefits, obstacles, and motivations to the adoption of this type of practices.

CONCLUSION

CSR has become a strategic necessity for companies, although its executives do not always understand its role in brand building and the importance of associating it with positive social actions, which may prove more complex than operating responsibly, since this requires the understanding of the multiple dimensions of CSR (Steenkamp, 2017). There are different positions regarding the benefits of CSR, and there are still skeptical voices that even deny its existence. Zero is that in the last decades, there are companies that have also paid attention to the broader social, economic and environmental conditions, in which the business also allows their momentum.

KEY TERMS AND DEFINITIONS

Communication of Social Responsibility: Communication of practices of an organization that contributes to economic, social development and environmental protection.

Community: Local grouping of people living in the same geographical area, united by common interests.

Corporate Social Responsibility: Corporate Social Responsibility or CSR can be considered in two ways: either as a theoretical or philosophical concept based on ethics and theories of right and wrong

doing by corporations and corporation decision makers, incorporating more recently not just the production, but also the social and the environmental dimensions; or as a practice by corporations of integrating in their behaviors, decision processes, strategies and communication the responsibility towards all stakeholders and the environment.

Creation of Shared Value: Policies and organizational practices that, besides contributing to the improvement of one's own, promote better social and economic conditions in the communities where they operate and market their products and/or services.

Local Development: It is the process of developing a territory, by actors who belong to it or whose activity in it has an impact, which implies the formulation of strategies, decision-making, and implementation of actions that allow civic participation, society.

Social Irresponsibility: Social irresponsibility for corporations can be defined as the increase of environmental costs, external costs for society, communities and stakeholders. It can include even shareholder as a subcategory of group who bear costs when the management of the organization is responsible for negligence or fraud or any behavior that can be considered non-righteous.

Social Responsibility: Contribution of any organization to sustainable development.

Stakeholder: Interested party of any organization (examples: owners, shareholders, investors, employees, suppliers, customers, unions, business and other associations, community where the company operates, competitors, press, municipalities, government, consumers).

Stakeholders Management: A process that comprises the identification, planning, involvement management, commitments, and control of stakeholders in any organization.

Territory: Space that in a certain time has its own limits and where social relations are established.

Enriching Organisational Knowledge of Corporate Social Responsibility From the Traditional African–Nigerian and Islamic Religion Perspectives

1.0 INTRODUCTION

Organisational knowledge of corporate social responsibility (CSR) has been dominated for decades by the American-European perspectives, although there are different perspectives to this debatable concept. This preference for CSR perspective from developed countries is obvious in the historical discourse of CSR. According to Carroll (1999), the long history of CSR could be linked to centuries of observed unethical behaviours and misconducts of corporations in the developed countries which later triggered agitations in the United States calling on the corporations to show more empathic concerns towards the society and the people. The agitation in favour of CSR became more pronounced in the 1950s through a widely celebrated treatise of the United States economist Howard Bowen titled “*Social Responsibilities of the Businessmen*” (Roy, 2010; Tounés, et al., 2011). Ismail (2009) opined that Bowen’s understanding of CSR is premised on the realisation that businesses could impact positively on the lives of the society through philanthropic initiatives and social-welfare projects.

Another perspective to the origin of CSR emanated from Tounés et al. (2011) who noted that the Protestant and Catholic groups were instrumental in the emergence of CSR through their philosophies of ‘public service’ and ‘stewardship’. The Catholic group preached to their members, particularly the property owners in industrial society, to imbibe the spirit of selfless service, empathy and contribution to support the society. It was the church’s philosophy as enunciated above that inspired ethical consciousness and led to the adoption of social responsibility.

For Mintzberg (1983), CSR had long existed as a consciousness to show concern for others in the society, a term widely known among Europeans as ‘noblesse oblige’, which literarily connotes ‘nobility obliges’. The root of ‘noblesse oblige’ indicates that it was a common French notion, used for describing ethical traits and worthy character displayed by a typical country gentleman, especially one who fulfils social obligations to the community. Obviously, CSR predated Bowen, it has been a noble English value practised by responsive individuals for ages. Bowen got credit for articulating CSR within the business context (Raimi, 2015).

Further exploration of CSR’s origin by Ismail (2009) indicates that CSR is an age-long practice traced to Oliver Sheldon, who wrote on the social performance of businesses in 1923 – a nuance that identified a strong link between social performances of business in the society and their market performances.

DOI: 10.4018/978-1-7998-3473-1.ch061

Similarly, it has been explained that before the discovery of CSR in Europe and America; there had existed a well-developed philanthropic model called Zakat - a form of religious tax enjoined on the rich as part of their social responsibility for supporting the poor (Roy, 2010). Whereas, Tounés et al. (2011) wrote that opinions differ on the origin of CSR. There are write-ups that traced the earliest proponents of CSR to the Protestants in the United States of America. In other words, the two prominent religious group (Protestantism and Catholicism) were instrumental to the emergence of CSR through rigorous advocacy of church's philosophy of public service that inspired ethical consciousness and a personal sense of responsibility among the congregants.

The African-Nigerian and Islamic perspective of social responsibility has been fairly explored by scholars in their quest to unveil indigenous African and Islamic ethical practices (Amaeshi et al., 2006; Helg, 2007, Le Grange, 2012; Raimi, 2014), but there is still need for deeper exploration in this direction. A separate CSR discourse from non-Western lenses is important because Africa has a different CSR agenda and challenges, which are quite different from those of the developed climes (Visser 2008).

For instance, the African-Nigerian ideals such Ubuntu and Omoluwabi which provide support for CSR need to be fully comparatively discussed. Salarzehi, Armesh & Nikbin (2010) wrote that evidenced-based research affirmed that good actions are embedded in people's beliefs and social culture and both shape their personality and attitude to social actions. In particular, religious belief largely influenced participation charitable giving and voluntary social action. Research found traces of social responsibility visible in the ethno-religious beliefs and the culture of Africans (Amaeshi et al., 2006). Also, the communal solidarity in Africa is built on selfless services, personal sense of responsibility and zeal to serve parents, relations, friends and community at large (Fajana, 2000).

From the foregoing background, the objective of the paper is to examine Organisational Knowledge of Corporate Social Responsibility from the Traditional African-Nigerian and Islamic Religion Perspectives in order to enrich the conventional American-European perspectives of CSR. Apart from the introductory section, there are five sections in this paper. The next section critically reviewed the literature spanning discussion on CSR from American-European Perspectives, CSR from Traditional African-Nigerian Perspective and CSR from Islamic Perspective. The third section clearly describes the hermeneutics theory of interpretation. The fourth section discusses the methodology employed in the study. The fifth section presents the emerging findings and thematic issues. The sixth section presents the conclusions and research implications.

2.0 BACKGROUND

2.1 CSR from American-European Perspectives

Western literature classified CSR into two continental perspectives, namely: (a) American perspective of CSR and (b) European-UK perspective of CSR. The American perspective of CSR is the philanthropic model, which advocates voluntary participations by corporations in societal programmes that they are favourably disposed to. Their common line of thought is that corporations should show philanthropic gestures through donations to societal initiatives voluntarily without being coerced.

However, the European perspective of CSR is typified as a citizenship model, which is anchored on the assumption that corporations must have an inclusive policy that integrates socio-environmental concerns into their business model because they are part of the larger society. This perspective of CSR is built on the ideals that corporations apart from their primary goal of profit-maximisation have ethical

obligations which include contributing towards the realisation of social welfare and environmental issues (Carroll, 1999; Snider, Hill and Martin, 2003).

The American and European perspectives of CSR have been re-christened by Matten and Moon (2004), as “explicit and implicit” frameworks respectively. The explicit CSR framework presupposes that corporations in the United States of America and continents that share this ideological posturing on CSR willingly partake in philanthropic initiatives or volunteering programmes like health-care provision, employees’ rights, and environmental protection as part of their CSR policies. The legal requirement for compliance with CSR is less stringent in America relative to what applies in Europe/the UK.

The implicit CSR framework on the contrary is a CSR posture of Europe/the UK, where corporations see their volunteering involvement in socio-environmental programmes as part of their legal responsibilities as a corporate citizen. Researchers contend that in the Europe-UK axis, the legal system assigns to corporations: “an agreed share of responsibility for society’s interests and concerns” (Matten and Moon, 2004: 9). It has been reported that the issue of CSR is taken seriously in Europe where CSR compliance is made a front-burner issue when the European Union initiated landmark policies on CSR and passionately implemented them for the betterment of the society. Besides, the United Kingdom appointed a substantive Minister for CSR in the Department for Trade and Industry. France made CSR a binding legal obligation on companies to disclose officially the impact of their CSR programmes in their annual reports. The Danish Government established the Copenhagen Centre for CSR research. The Netherlands adopted the French model, requesting corporations to comply with the principles of environmental sustainability and ensure their annual reports reflect philanthropic initiatives in line with the Guidelines for Multinational Enterprises designed by the OECD, to which Netherlands is a signatory (Luetkenhorst, 2004; Raimi, 2015). Moreover, within Canada’s mining industry, when voluntary CSR compliance and self-regulation failed, the civil societies, NGOs and host communities forced the government to make compliance a binding and enforceable obligation like Europe through promulgation of Bill C-300. The Bill C-300 seeks more pragmatic accountability and “punitive measures” for offending corporations (Hart, 2012:6).

2.2 CSR from Traditional African Perspectives

The African perspective of CSR has been fairly explored by scholars in their quest to unveil indigenous African and Islamic ethical practices (Jackson, 2004; Amaeshi et al., 2006; Helg, 2007, Ajadi, 2012, Raimi, 2014), but there is still need for deeper exploration in this direction. African perspective of CSR is deeply rooted African moral theory, which as a philosophy prescribes actions that are right and desirables, and which promotes living harmoniously and peacefully with other members in the society. It extends also to imbuing in the people the practice of honouring communal relationships and maintaining solidarity (Metz & Gaie, 2010). Within the African moral theory, CSR should be understood as an attempt to develop a collective approach to problem-solving and the need to elicit social impact from diverse groups such as the extended-family system and the village community. It is evidently clear in African philosophy that being socially responsible to the people and the society is a way of life that had been embedded long before the formalised Western perspective of CSR (Phillips, 2006; Roy, 2010; Raimi, 2015).

Comparatively, African CSR philosophy is altruistic, as it seeks to provide social support for disadvantaged members of the society, whereas the Western CSR philosophy to large extent seeks to provide a mask for the limitless pursuit of profit and power by the corporations and their owners (The Economist, 2005). Helg (2007) discussed a number of African ideals such African Renaissance, Ubuntu and

Omoluwabi which functionally and structurally all align with principles of CSR. Another exploratory study found traces of social responsibility in the ethno-religious beliefs among Africans where the culture of charity giving is prevalent (Amaeshi et al., 2006). The communal solidarity in Africa is structurally built on selfless services, personal sense of responsibility (PSR) and empathetic zeal to serve parents, relations, friends and community at large (Raimi, 2015). For instance, in the traditional Igbo society, the communal solidarity is a noteworthy social responsibility. According to Fajana (2000:19) “the economy of the various states which make-up modern Nigeria was basically a subsistence economy and customs had established the practice that people serve their parents, village heads and the community without remuneration [doing good]. On a given day, people went and work for a particular individual. Through the day, the man they serve was responsible for their food and drink. On another day, the man returned the service and it went on until everybody in the group was served.” The above quote affirms that the spirit of social consciousness and solidarity had been firmly entrenched in Africa several decades before Bowen’s conceptualisation of CSR in the United States of America.

Another African ideal that explicates CSR, is the Ubuntu philosophy. Ubuntu is an empathic philosophy with root in the languages of Zulu and Xhosa of South African (Dartey-Baah and Amponsah-Tawiah, 2011). Ubuntu is a consciousness that inspires Africans to be concerned about the wellbeing of their fellow Africans (Mbigi and Maree, 1995; Helg, 2007). It also means “humanity towards others” and “the belief in a universal bond of sharing that connects all humanity” together (Helg, 2007:44). Ubuntu is founded on six core values, viz:

- a) Group solidarity (that is, all age groups/associations work in teams for mutual benefits),
- b) Conformity (that is, every individual must align with norms, mores, rules and regulation),
- c) Compassion (that is, every individual must have empathy for fellow mortals),
- d) Respect (individuals must give regards to fellow humans and traditions),
- e) Human dignity (freedom, liberty and self-esteem)
- f) Collective unity.

The focus of Ubuntu, like CSR, is the utmost concern for humanity, community, society, and people living therein as well as their traditional norms/values. Elkin and Strach (2002:11) describe Ubuntu succinctly as the: “African belief that a person becomes human through other people (umuntu ungumuntu ngabantu).” Another description of the meaning by Mbigi and Maree (1995:41) is “I am because We are.” It is therefore, a philosophical ideal that exalts collectivism above individualism. Le Grange (2012) explained and applauded the concept of Ubuntu because it embeds humanness, and potency to restore ecological stability to the damaged planet and battered society. The ideal of Ubuntu should be “invoked to contribute to the healing of the three ecologies—how healing of the social might transversally effect healing of nature and the self.” (p.56). Africans in South Africa specifically and others suffered erosion of their humanness (nature, society and self) as a result of centuries of colonialism and decades of oppressive and repressive apartheid regimes (Le Grange, 2012). Comparative analysis indicates clearly that Ubuntu accommodates the Triple-bottom-line wellness, that is, the three elements of Ubuntu (nature, society and self) explicate the Triple-bottom-line (economic, social and environmental considerations).

Related to the above is the African-Nigerian perspective on CSR called ‘Omoluwabi’ – a rich ethical nuance from South-West of Nigeria. Omoluwabi is purely a Yoruba philosophical term used for describing the worthy character possessed by an individual, group and nation (Helg, 2007; Dartey-Baah, and Amponsah-Tawiah, 2011). According to Omoluwabi Social Cultural Group (2010), the term Omoluwabi is an age-long Yoruba social concept that describes seven core traits of male and female such as Hard-

work; Honesty; Integrity; Fairness; Egalitarianism; Respect for Elders and Constituted Authority; and Fear of God. In all there are seven core attributes of Omoluwabi. These cherished traits are expected to guide the actions and inactions of people, groups and nations.

For the Yoruba people of South-West of Nigeria, the concept of Omoluwabi is valuable ethical concept. Dartey-Baah and Amponsah-Tawiah (2011) noted that there are seven attributes of the Omoluwabi construct. However, when critically viewed in line with the organisational knowledge discourse, the concept of Omoluwabi functionally resembles CSR. Like CSR, the Omoluwabi ideal shapes the society and strengthen people's morals "to contribute to the good, progress and development of the Yoruba nation [...] to influence the landscape through activities that will foster unity amongst the Yoruba nation and enhance economic growth of our people irrespective of location" where they may live (Omoluwabi Social Cultural Group, 2010). At global level, Ajadi (2012) noted that Omoluwabi is the reconstruction of organised indigenous principles, values and traditional codes as development paradigms considering the vantage position of Nigeria, its population and status in the world. Omoluwabi as a management construct emphasises renewal of trust, cooperation as a way of building an efficient and effective world-class management system hinged on indigenous foundational principles otherwise called Africanisation.

2.3 CSR from Islamic Religion Perspectives

Asian continent that housed the Islam has a rich history of strong sense of community and empathetic activities (Phillips, 2006). A number of scholars have written on the congruence between Islam/Ethics of Shari'ah Law and CSR (Al-Qardawi, 1973; Brammer, Williams and Zinkin, 2006; Dusuki, 2008; Gill, 2011; Mohammed, 2007; Mohammed, 2013). Undoubtedly, there are ethical provisions in Islamic jurisprudence serving as a regulatory framework for businesses, or what people otherwise call the dos and don'ts of business transactions (Dusuki, 2008). Moreover, Taman (2011) stated that the ideals and principles of CSR are consistent with Islam. CSR often finds acceptability from Muslim businesses and managers it is situated within the framework of worship and rewardable social action (Raimi, et al, 2014). In Islam, CSR assumes a broader spiritual significance because it is a philosophy that motivates man as an individual to interface with the larger society and fellowmen; its depth extends beyond the Western strategic or instrumental goals of flagging social actions to enhance goodwill or boost long-term financial performance of companies The Muslims as social beings therefore must have concerns for people, plants, animals and environment, and that social responsibility is a moral and religious obligation that cannot be ignored, nor disregarded regardless of financial positions of their businesses (Dusuki, 2008).

The growing number of scholarly articles on CSR and Islam, which established a strong link between Islam and ethical issues, is an acceptance of the fact that CSR theoretically and practically align with Islam (Taman, 2011). According to Gill (2011), Islam is a unique religion with a well-developed Code of Ethics that provide guidance for ethical and social behaviour of humans. The concept of CSR although relatively new in industrial society, it been firmly rooted in Islam as Zakat over 1400 years ago. To Dusuki (2008), CSR assumes a broader spiritual significance in Islam because it is a philosophy that motivates man to support the larger society and fellowmen through Zakat; its depth in Islam extends beyond the Western strategic or instrumental goals of flagging social actions to enhance goodwill or boost long-term financial performance of companies (Dusuki, 2008). Therefore, the practice of charitable giving (Zakat) is desirable behaviours that Muslims as individuals and corporate entities have been instructed by God fulfil their obligations the people, environment and the larger society. Allah says:

“And render to the kindred their due rights, as (also) to those in want, and to the wayfarer: But squander not your wealth in the manner of a spendthrift. Verily spendthrifts are brothers of the Evil Ones; and the Evil One is to his Lord (himself) ungrateful.” (Al-Hilali & Khan, 2018, Qur’an 17:24-25).

“Take Sadaqah (alms) from their wealth in order to purify them and sanctify them with it, and invoke Allah for them.” (Al-Hilali & Khan, 2018, Qur’an 9: 103).

“Corruption has appeared in the land and the sea on account of what the hands of men have wrought...” (Al-Hilali & Khan, 2018, Qur’an 30:41)

“And do no mischief on the earth, after it has been set in order...” (Al-Hilali & Khan, 2018, Qur’an 7:56)

“When he turns his back, his aim everywhere is to spread mischief through the earth and destroy crops and cattle...” (Al-Hilali & Khan, 2018, Qur’an 2:205)

Contextually, Zakat differs from Sadaqat. Zakat is a compulsory obligation payable annually by Muslims at the rate of 2.5% on net incomes that is benchmarked by Islamic law at 20 Dinar worth of gold or 200 Dirham worth of silver, while Sadaqah is a voluntary charity giving out anytime to support the less privilege in the society (Raimi, Bello and Mobolaji, 2010). Zakat has also been described a pillar of the Islamic religion instituted purpose for empowerment and creating social justice in the Muslim societies (Jawad, 2009). Zakat and Sadaqat perfectly fit CSR because they address social, economic and environmental concerns of the community (Raimi et al., 2013). Unlike CSR, the Zakat is built on a theological foundation of the Laws of God, hence non-compliance is viewed as “an affront to God’s will, with serious consequences on defaulters in this world and in the Hereafter.” (Dusuki, 2008: 22).

Another way of reflecting social responsibility in Islam is through Waqf. According to Raimi, Patel and Adelopo (2014), the term Waqf is often defined as “valuable property and tangible assets set aside by the legal owners as gifts to Allah and His cause and for the benefit of humanity. Waqf also connotes an endowment/foundation established by the affluent individuals purposely to provide free relief services and solace to the vulnerable members of the society.” (p.234). It could functionally be described as a surrendering and sacrificing one’s personal property for public affairs and wellness; it is the Islamic alms-houses and reflects social entrepreneurship in Muslim countries (Salarzehi, Armesh & Nikbin, 2010). Religious Waqf allocates property to mosques and religious schools as endowments. This allows for sustainability of the activities of the mosques and religious schools. However, the philanthropic Waqf is dedication of property to the society for humanitarian purposes for large scale benefits to the poor and marginalised public. This type of Waqf could be used to set up educational centres/school. Library, hospitals, animal care, care for the ecosystem, road and recreational facilities. Whereas, Family Waqf is dedication of property by parents for the upkeep of their children and dependants after death (Raimi et al, 2014; Salarzehi et al, 2010).

From the mainstream Islamic viewpoints as discussed above, CSR is a voluntary duty like the charity called Sadaqah; it is an act of empathy carried out by socially responsive individuals and groups as an act of worship with the mind-set of pleasing Allah and giving back to the society. From the foregoing, CSR and Islam connect because Islam gives preference to human wellness by instituting social security systems such as Zakat, Sadaqat and Waqf to bridge gaps and maintain socio-economic equilibrium between the rich and the power (Raimi et al, 2013; Dusuki, 2008). Therefore, considerations for social, economic and environmental wellness of humans, minerals, plants and animals (broadly summarized

as social, human and natural capital elements) are recognised personal and corporate responsibilities in Islam. In general, the laudable tenets of Islamic religion are consistent with modern business ethics including are the ‘Ten Principles’ of responsible business codified in the UN Global Compact (Zinkin, 2007; Williams & Zinkin, 2010). It is instructive to state that CSR is not at variance with Islam because apart from Zakat which is compulsory, there is opportunity for wealthy persons and organisations to pay extra levies on Muslims and corporations beyond the obligatory Zakat (Al-Qardawi, 1973).

3.0 HERMENEUTICS THEORY OF INTERPRETATION AND CSR

For this study, hermeneutics provides the needed theoretical underpinning. This theoretical underpinning finds support in the view of Crotty (1998) that, hermeneutics is not a research method, but a theoretical perspective that extends to a methodology, which underpins the methods employed in a particular study. Similarly, Bleicher (2017) opined that hermeneutics is loosely the theory or philosophy of the interpretation of meaning in the philosophy of social sciences, the philosophy of art and language and in literary criticism. In other words, it is the “art and science of interpretation” (Ezzy, 2002: 24). Therefore, hermeneutics theory is a critical textual interpretation about a concept for qualitative study, for the purpose of unveiling the philosophy or hidden understanding contained in texts.

As a theory, hermeneutics has undergone fortification over time as Ricoeur’s hermeneutic theory (Geanellos, 2000), hermeneutics and phenomenology (Tan, Wilson & Olver, 2009). But, Kinsella (2006) explained that, hermeneutics is a useful theoretical construct for qualitative exploration and critical investigation for interpretative research with a view to having indepth understanding of objects of inquiry. Hermeneutics is also desirable to help bridge the congruence between the philosophical foundations of a research and the methodological processes for validating research findings through textual analysis. The congruence between philosophy, methodology and method is actualized through a forward transition from naive understanding of the text by the researcher, to a deeper understanding of parts of the text in relation to the whole and finally an understanding of the whole of the text in relation to its parts a process termed the hermeneutic circle (Geanellos, 2000; Tan, Wilson & Olver, 2009).

With specific reference to CSR, hermeneutics theory of interpretation is applicable because theorists argued that, it helps in the interpretation and description of human experience in order to understand the central nature of such experience (Evans & Hallett, 2007; Tan, Wilson & Olver, 2009). Besides, a number of conceptual, theoretical and empirical studies had been conducted to provide insights into the philosophy of CSR essentially from Western perspective, but the contribution from the Traditional African-Nigerian and Islamic Religion Perspectives is few and peripheral. An enriched organisational knowledge of CSR from the latter is imperative leveraging hermeneutics theory of interpretation. At the end of the hermeneutics, richer insights on CSR philosophies from the Traditional African-Nigerian and Islamic Religion perspectives give comprehensive understanding and consequently opens new possibilities about organisational knowledge of CSR.

4.0 METHODOLOGY

Exploiting the Hermeneutics Theory of Interpretation as explained above, this research adopts a qualitative research method because the phenomenon of inquiry is veiled, hidden and unclear, it therefore need to be investigated, understood and interpreted. The authors sourced the required qualitative data from

journal articles, Islamic texts, other textual sources as well as relevant online resources on the subject. The extractions from sundry sources above were subjected to content analysis to gain new understanding, meanings, themes and insights from non-Western texts and scholarly works on CSR using content and thematic analyses (CTA). This methodological approach aligns with previous studies that used hermeneutics and phenomenology such as Tan, Wilson & Olver (2009) and Bleicher (2017).

4.1 Findings and Discussions of Thematic Issues

From the content and thematic analyses of scholarly texts (leveraging hermeneutics theory of interpretation), this study found that the concept of CSR had long existed in the philosophies of Traditional Africans and Islamic Religion as Ubuntu, Omoluwabi, Communal Solidarity, Zakat, Sadaqat and Waqf. The African-Islamic perspectives of social responsibilities correlate structurally and functionally with the American-European CSR perspectives that have dominated the academic landscape for decades. The findings therefore demystified the widely-held view that CSR is a new organisational knowledge in Africa and the Muslim World. Comparatively, the Western perspectives have consistently undergone refinement and reinvention in theory and applications by academics and practitioners in the society, whereas, the non-Western perspectives have largely remained under-researched and static. Although social actions had been entrenched in the cultural norms of Africans and Muslims with different names, and were deployed to tackle poverty and achieve social equilibrium in a number of ways ranging from training, micro-credit support for the poor, apprenticeships, infrastructural development in the communities, as well as providing welfare support services to the marginalised and other economically disadvantaged groups (see Table 1).

With regards to the meanings of CSR, the understanding across the three perspectives overlap. Western perspective views CSR as a voluntary obligations of companies to give back to the society. African perspective of CSR on the other hand is also a voluntary obligation carried out by individuals, groups and communities to provide social support for the disadvantaged members in the society. Islamic perspective of CSR reflects in Zakat, Sadaqat and Waqf. While the Zakat is a compulsory obligation, the Sadaqat and Waqf are voluntary acts of empathy carried out by socially responsive individuals and groups as an act of worship with the mind-set of pleasing Allah and giving back to the society (see Figure 1). The Muslims derived their CSR perspectives from the Eternal Law (Scripture-based).

On the issue Who takes on CSR? The three perspectives differ slightly. While it is strictly the corporate organisations in the Western perspectives, the African-Nigerian and Islamic perspectives of CSR accommodate individuals, groups and businesses to be involved in socially responsible behaviour.

For the African, social responsibility assumes different forms such as Omoluwabi, communal solidarity and Unbutu (Figure 2). Omoluwabi is an ideal that shapes the society and strengthen people's morals to contribute selflessly towards the society and the people for the overall objective of stimulating peace, progress and development in the Yoruba nation. In Igbo land, the concept of communal solidarity is particularly common, it is an ideal that is structurally built on selfless services, personal sense of responsibility (PSR) and empathetic zeal to serve parents, relations, friends and community at large. Among the South Africans, the concept of Unbutu is institutionalised, highly respected and practised. Unbutu reflects concern for humanity, community, society, and people living therein as well as their traditional norms/values – a perspective that exemplified corporate citizenship model in western literature. Ubuntu's humanness has three elements: nature, society and self, which fits perfectly as the Triple-bottom-line (economic, social and environmental considerations). The African perspectives of CSR is focused on people and desire for a distributive justice in the society.

5.0 CONCLUSIONS AND IMPLICATIONS

The paper sets out to examine organisational knowledge of CSR from the Traditional African-Nigerian and Islamic Religion Perspectives in order to enrich the conventional American-European perspectives of CSR that have dominated the academic landscape for decades. Using a qualitative research method,

Table 1. Thematic Comparison of Three Perspectives of CSR

Features of CSR	Western CSR	African CSR	Islamic CSR
Meaning	It is a voluntary obligation of companies to the society as corporate citizen.	It is a moral duty that individuals, businesses and communities owe fellowmen.	It is a religious obligation that Muslims as individuals, groups and businessmen are expected to fulfil for the pleasure of God.
Who takes on CSR?	Businesses	Individuals, Groups and Businesses	Individuals, Groups and Businesses
Drivers of CSR	Reputation-building Government wavers Greenwashing Strategic marketing	Social integration Empowerment	Fear of God personal sense of responsibility, support for the disadvantaged
CSR: Voluntary or Obligatory?	Voluntary (US) Obligatory (Europe)	Voluntary	Sadaqah (Voluntary) Zakat (Obligatory) Waqf (Voluntary)
Degree of compliance	Very high among big companies Low among SMEs	Very high among individuals, groups and communities	Very high for (Sadaqah) Low for Zakat Modest for Waqf
Domains CSR	Social, Economic and Environmental	Social, Economic and Environmental	Social, Economic and Environmental
CSR programs	Donations, Volunteering and Projects	Donations, Volunteering and Projects	Donations, Volunteering and Projects
Impact of CSR	Improved financial performance, Customer loyalty Competitiveness Enhanced reputation	Poverty reduction Wealth redistribution Social equilibrium Communal solidarity Bonding	Poverty reduction Wealth redistribution Social equilibrium Love of God Social Services
Theory of CSR	Relativism (Self-Interest Based), Utilitarianism (Cost-Benefit Approach)	Distributive Justice (Justice-Based Wealth and Benefits Approach)	Eternal Law (Scripture-based).

Source: Authors' Extractions from the reviewed literature

it was found that the concept of CSR had long existed in the philosophies of Traditional Africans and Islamic Religion as Ubuntu, Omoluwabi, Communal Solidarity, Zakat, Sadaqat and Waqf. These African-Islamic perspectives of CSR correlate perfectly with the conventional American-European perspectives. The findings therefore demystified the widely-held view that CSR is a new organisational knowledge in Africa and the Muslim World. In particular, the ideals of CSR had been entrenched in the cultural norms of Africans and Muslims, although with different names. CSR initiatives in these climes include poverty alleviation, training, micro-credits support, infrastructural development and other social services. Practically, this paper is a contribution to theory and practice of CSR in the field of organisational management and Islamic management. The paper has enriched organisational knowledge in the field of CSR both in theory and practice. It has also provided an integrated understanding of CSR across three perspectives, recognising different continental ethical values. The dominant Western perspectives of CSR, fuelled lack of a comprehensive global understanding within which a broader perspective of CSR ought to be positioned and projected.

6.0 FUTURE RESEARCH DIRECTIONS

Further research is encouraged to unveil more African CSR ideals that are buried in cultural practices and those that positively manifest in the day-to-day norms of Africans that are worthy of being investigated, strengthened and reinvented for adoption in the field of comparative management.

KEY TERMS AND DEFINITIONS

Corporate Social Responsibility: This is the voluntary obligation that companies owe to the society as a commitment to giving back to the society.

Islam: This is the religion and the way of life of people that follow the principles and practices of Qur’an and Hadith at personal, organisational and societal levels. Islam is a unique religion with a well-developed Code of Ethics that provide guidance for ethical and social behaviour of humans.

Organizational Knowledge: This refers to specific knowledge emerging from the collective experience of organisation as an entity as well as from the individual experience of organisational members for the purpose of achieving set objectives.

Sadaqat: Sadaqah is a voluntary charity giving out anytime to support the less privilege in the society.

Zakat: This is a compulsory obligation payable annually by Muslims at the rate of 2.5% on net incomes that is benchmarked by Islamic law at 20 Dinar worth of gold or 200 Dirham worth of silver.

Understanding Corporate Social Responsibility of Commercial Banks in Nepal

Raghu Bir Bir Bista

Tribhuvan University, Nepal

1. INTRODUCTION

This paper examines Corporate Social Responsibility (CSR)'s nature and practices of the commercial banks in Nepal, where the corporate sector has been expansionary in all sectors after Nepal initiated the economic reform 1992 to liberalize all sectors of the economy to the corporate investment, except few sensitive areas (communication and security)(MoF, 2017). Its good result occurs in the commercial banking sector in terms of number, services and investment. NRB (2017) and MoF (2017) report 28 Commercial Banks and 48 Development Banks. In 1990s, its numbers were only six. Until 2017, its growth rate is 400 times in the Commercial Banks and 800 times in Development Banks. Their net profit figures are very impressive in the top competitive financial market. At some extent, these banks have initiated social responsibility, although the industrial policy has made it voluntarily, unlike India and USA where corporate social responsibility is mandatory. In India, the corporate sector has to spend at least 2 percent of their annual profit in the society as corporate social responsibility. In USA, it is also 1 percent legal and ethical mandatory. Despite its voluntary nature, the well aware consumer expects their Commercial Bank's significant contribution to the society as their social responsibility in accordance with international norms and values of the corporate governance. There are few handful literatures in Nepal but almost have focused on MNC. In banking sector, there are none of literatures dealing such issue. In the context of growing CSR activities and practices of the Commercial Bank, its examination is relevant to understand in depth its nature, characters, size, trend and pattern for its promotion and development in these sectors.

This paper is organized into the following sections: Section 2: Objectives, Section 3: Literature Review, Section 4: Theoretical Framework and Section 5: Data sets and Methodology, Section 6: Results and Discussions, Section 7: Conclusions.

2. OBJECTIVES AND METHDOLOGY

The paper has main objective to examine CSR's nature and practices of the commercial banks in Nepal. In addition, the paper analyzes structure and trend of their CSR budget in Nepal. Further, the paper explores its size and CSR and Profit ratio and identifying their priority areas.

3. CSR SCENARIO AND PRACTICE

3.1. Concept of CSR

CSR is inevitable ingredients of the successful, efficient and giant corporate governance in the world. In this context, debate on CSR is still going on at the different levels in the different forums, along with mandatory or voluntarily its practices. The concept emerged in 1917, when Henry Ford initiated social responsibility in terms of value of all stakeholders' interests as well as the social welfare of employees and shareholders (Lee, 2008 and Meredith, 1999). It was not emotional. It was a business perceptive and practice to be good corporate citizen. At some extent, the company had such practices in all over the world. Immediately after the World War II, the corporate business acknowledged the need to commit some of their profits to social causes. May be its cause would be social, economic and political turmoil(1930s-1950s) and the reactionary movement of the citizens to fight against the abuse of power, corruption, tax evasion, discriminatory pricing, and lack of protection for workers and consumers and other anti-social practices by industries(Afful, 2003). Its focus was only social cause. It did not focus on the issues of workers, customer and community. Its reflection is still even in 21st century, when they do not treat their workers, customers and their communities any better. Meanwhile, there is positive practices in which the company owners having human attitude to their workers and supported social causes, do so for religious or charitable purposes. However, distributing food and money to the poor during festivals cannot be called CSR (Afful, 2003). The Reputation Institute (2017) has listed higher CSR companies out of total companies (170,000) of the world such as Lego (1st Rank), Microsoft(2nd Rank), Google(3rd Rank), Walt Disney Company(4th Rank), BMW(5th Rank), Intel (6th Rank), Robert Bosch(7th Rank), Cisco System (8th Rank) and Rolls Royce(9th Rank). Such rating has improved their value induced sales, loyal consumer and employees more than lower rating CSR companies. Further, Sen et al.(2006) noted the growth of CSR activities and its influence on sales growth and the employment and investment. Carmeli (2005) mentioned it as a sustainable competitive advantage. Therefore, it has become ingredients of corporate governance for competitive advantage.

Academic perspective attempted on CSR in 1932, when Dodd (1932) and Berle (1932) published their article on "For Whom Are Corporate Managers Trustees?" in a Harvard Law Review. In 1953, Bowen published a book, Social Responsibilities of the Businessman focusing on the relationship of corporation with society and need of business ethics (Carroll, 1979). In 1970, Milton Friedman (1970) continued this debate through his article on "The Social Responsibility of Business Is to Increase Its Profits," in the *New York Times Magazine*. Thus, CSR has received public and academic attention for social interest. Such evolution of academic perspective has contributed its modern concept. The literatures (Carroll, 1999; Engardio et al. 2007; Hart, 1995; Holmes and Watts, 2000; McWilliams and Siegel, 2001; Nicolau, 2008; Tsoutsoura, 2004) mention CSR as the activities making companies good citizens who contribute to society's welfare beyond their own self-interests. In addition, Elhauge (2005) explains CSR as *sacrificing profits in the social interest*. In simple, it is social work of the corporate sector in the society. Similarly, Graff Ziven and Small (2005), Portney (2005) and Reinhardt (2005) in their papers have offered similar arguments consistently. If we examine it, we can find that it is normative nature and general statement in which the corporate sector binds to contribute in the society through using profit share but it must be in accordance with the social interest. It means not specifically whatever social goods desired by the society, which may be either environment or infrastructure or social sectors (health or education or sanitation).

3.2. CSR: Mandatory or Voluntarily

Some literatures (Griffin, 1998; Afful, 2003; Kootz and Weihrich, 1990 and Kreitner, 1999) have discussed whether CSR is mandatory and voluntarily. Griffin (1998) defines it as the set of obligations an organization has to protect and enhance the societal context in which it functions. Social responsibilities of business mean responsibilities of business towards customers, workers, shareholders and the community (Afful, 2003). The government of India (2017) mentioned it as mandatory in the Industrial Policy. Koontz and Weihrich (1990) and Kreitner (1999) argue in the similar way in their papers. EU (2001) focuses more on the integration of social and environmental interest. However, the government of Nepal (2017) explains it voluntarily by giving freedom to the corporate sector. Thus, CSR is in both mandatory and voluntarily in accordance with the country's perspective and policy on the corporate governance.

Figure 1. CSR Framework

3.3. CSR: Its components Pyramid

Sriram and Achick (2003) conceptualize categorically on CSR issue with the statement, "Conceptually, CSR is a bridge that links corporate and social interests in two ways. First, the firm is presumed to have other goal that it strives to achieve in addition to its shareholder wealth maximization goals. Second, groups other than stockholders (e.g. employees, customers, and community) are perceived to have a vested interest in the consequences of firm's actions." We can conclude CSR as investment on business and social interest as well as environmental interest. Schwartz and Carroll(2003) explained its three components: economic, legal and ethical in their conceptual framework.

CSR Practices in the Corporate Governance

CSR practices in the Corporate Governance are heterogeneous in the world. Its determinant factors are generally legal provision, ethical obligation and value creation as shown in the pyramid of CSR. European Countries and USA have clear and comprehensive corporate laws about CSR that is the corporate bodies sacrifice their profit for their public social welfare and business expansion.

For example, every US state recognizes the right of businesses to make charitable contributions. Seven states allow charitable donations regardless of corporate benefit, and nineteen other states allow donations that benefit the business or advance the public welfare (Choper, Coffee, and Gilson, 2004). Statutes in the remaining 24 states (including Delaware) include similar language, but without legal clarification about whether donations are permitted, when they do not benefit the firm (Donohue, 2005). Therefore, CSR is legally mandatory to the corporate body. Similar practices occur in European countries, where the stakeholder's participation is endorsed in CSR practices. Europeans have sought to incorporate CSR into their investment climate, both at the institutional and individual level (Sutton, 2004), and in strong social democracies, such as Germany and France, stakeholders (particularly employees) have much stronger legal positions than in the United States (Roe, 2000). Corporations in Europe and Asia are also more likely to have a few large shareholders, who may take social responsibilities seriously, particularly those towards employees (Roe, 2000). Further, European countries have focused more on the inclusion of stakeholders for CSR's transparency and effectiveness.

CSR is emerging issue in developing countries, where subsistence agriculture dominates to Industrial sector and traditional business patterns led to the corporate sector. It is new experience to the corporate sector. After the liberalization to FDI, MNC has brought such concept and practices at some extent in accordance with their mother countries norms, values and systems. Its practices seem to be contrast and dark more than developed countries. Literatures of CSR in developing countries (Human Development Index (HDI), Transparency International and Global Integrity) mentions poor CSR because of the absence of CSR provision in the corporate law. May be the government has not such way of thinking in the policy formulation. May be it is distracted by the lack of good governance, political stability, democratic issue, corruption and supremacy of law. Therefore, the lack of CSR provisions in the corporate law is a big issue. In this critical context, Multinational Company (MNC) has violated their mother country's CSR norms, values and system, except making a profit by ignoring all these issues. Therefore, CSR practices of MNC are unexpectedly poor and critical. Therefore, additional CSR of MNC is only a dream to the government and the people.

3.4. CSR Practices in Nepal

CSR is not new issue in Nepalese society, when we observe the evidence. In Medieval and Modern Period, CSR was a major ingredient of Nepalese society and its behavior. Its practice was individual level of Merchant and Businessman to get business as well as good will value. It was not profit based. In general, such social responsibility was philanthropy nature and pattern in which road, tap, schools, health post, public place, open place, the establishment of temples and other infrastructure having social and religious value and concern (Bista, 2016). It was religious obligation, except business obligation. Its impact was good but was limited. Since 1990, modern CSR has been appearing in the corporate sector, although the corporate law has not mandatory provision of CSR, like as India has. CSR relates to corporate sector as business ethics and responsibility. Nepal(2006) in CSR report of FNCCI (2006) perceives CSR as the commitment from business enterprise towards sustainable economic development, creating

good working environment for employee/ their families and local community / society welfare at large to improve the quality of life. Furthermore, the employees should be considered as business' best assets and ambassadors. Employee, shareholders, customers, government, civil society consider environment as important components of the CSR. The company acts either preventive or proactive is an act of CSR.

With the growing pressure from civil society organizations and other groups, the corporate sector in Nepal is taking social responsibility seriously (Afful, 2003). For example, FNCCI has in cooperation with the UN women's organization is supporting children education. Individual companies have also been involved in development activities such as Micro hydropower projects, biogas projects, environment, health and agricultural program. However, real picture is that most corporate sector organizations are aware of the socio-economic conditions of their surrounding communities. Unfortunately, they do not respond to it unless there is pressure. The relationship between the corporate sector and communities has still not been clearly defined (Afful, 2003). Bista (2005) mentioned some extent of CSR in MNC firms in Nepal.

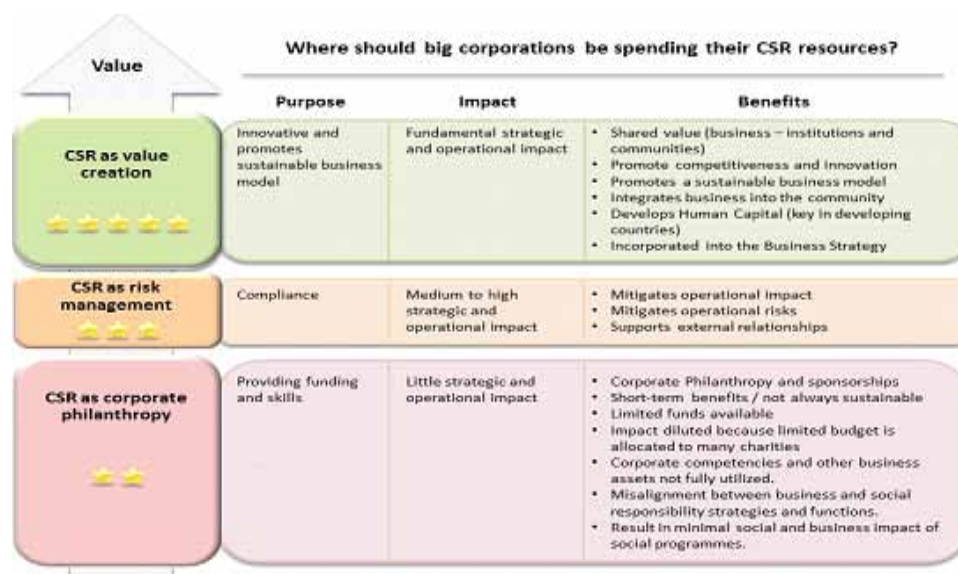

Observation on corporate law and policies of Nepal provides three tier legal and policy literatures such as Industrial Policy 1993, Foreign Direct Investment Act and One Window Policy 1992 and Interim Plan 2007-2010. All have mentioned CSR but not mandatory.

4. METHODOLOGY

4.1. Conceptual Framework

Corporate Social Responsibility (CSR) is inevitable ingredient of corporate governance of the corporate sector to create corporate branding value in the market and to make the consumer loyal on products. It is called corporate citizenship or responsible business. Carroll (1999) explains CSR having economic responsibility, legal compliance, ethical and philanthropy. It has three objectives: value creation, risk management and philanthropy.

Figure 2. CSR Framework

Multinational companies (MNCs) or Corporate are profit motive. Its profit function is to maximize net profit at large scale. In principle, such business should be responsible. It means the corporate should be responsible to the society. Then, the corporate business will be sustainable with value and good response. In order to make responsible business, the certain percentage of profit is spent to the society. Therefore, CSR depends on the corporate governance and profit. After creating value, CSR has positive impacts on sales growth and profit. Therefore, profit depends on CSR.

Figure 3. Conceptual Framework of CSR

Source: Bista (2018)

4.2. Data Sets and Data Collection Method

Responding above these objectives stated in this paper, we employed explorative and descriptive research method. Data sources of the paper was primarily secondary data and information collected from the published documents of the commercial banks, particularly their published audit report from 2008 to 2017. Out of total commercial banks (28), we selected six commercial banks by using purposive methods. The selected commercial banks included three different banks: joint venture banks (NABIL), private banks (Nepal Investment Bank, Mega Bank, Siddhartha Bank and Civil Bank) and public banks (Nepal Bank Limited). All public Banks provide their services to all 75 districts and almost villages. The joint venture and private Banks have covered only 70 percent districts, except Himalayan districts.

As supplementary, the primary data about CSR perception of stakeholders was collected at two levels: 60 staffs of the Banks at first stage and 100 stakeholders at second stage. The first level information was collected through telephone interview method. The second level information was collected through structure questionnaire survey in Kathmandu.

5. RESULTS AND DISCUSSION

5.1. CSR Characteristics

CSR of the Commercial Banks is inevitable to their corporate governance and corporate development. The Commercial Banks have conducted CSR at some extent in the country for a long time. For their value creation and social relationship, these activities are important events. At academic and business level, these activities are concern in the context of International norms, values and system of Multinational Company and Social Development Goal (SDG). In this context, there is a query about their CSR characteristics for understanding CSR activities, status, pattern, size and institution. In order to capture the CSR characteristics, the study has employed eight indicators: No of Years for CSR, Regularity in some years, CSR size, percentage of profit, CSR team, CSR events, CSR disclosure and the year of establishment.

Out of 28 Commercial Banks, the sample Banks are well established with commercial good will in the financial market. There are three banks before the Structural Adjustment Program (SAP) 1990: Nepal Bank (1937), NABIL (1984) and Nepal Investment Bank (1986). Nepal Bank was established in Rana Regime; meanwhile NABIL and Nepal Investment Bank were immediate after Structural Adjustment Program (SAP) 1980. The remaining three banks were established after the SAP II: Mega Bank (2010), Siddhartha Bank (2002) and Civil Bank (1993). When we talk about the age of the Commercial Banks, their age are 81 years age of Nepal Bank, 34 years age of NABIL, 32 years age of Nepal Investment Bank, 25 years age of Civil Bank, 18 years age of Mega Bank and 16 years age of Siddhartha Bank. Based on CSR disclosure, these banks have given least years for CSR activities. Out of 81 years age, Nepal Bank has given a year for CSR. It is 1.23 percent year. Similarly, when we observe CSR activities, there are 5 years of NABIL(14%), 4 years of Mega Bank(22%), 3 years of Nepal Investment Bank(9%), 2 years of Siddhartha Bank(12.5%) and 1 years of Civil Bank(4%). Thus, the Commercial Banks have allocated their time for CSR activities. It indicates CSR at least priority in the Commercial Banks.

When we observe Multinational Company like Microsoft, Google, MacDonald, Apple, etc., CSR activities are regular and consistently continuous, like as their operational activities so that the Corporate has positive impact not only at the society but also at business community and at the government. Its indirect effect will fall on the business promotion and then on the sales growth and customer's growth. Based on CSR disclosure of the Commercial Bank, CSR activities have irregular and discontinuous pattern since their establishment years. However, when they have initiated CSR activities, CSR is regular and continuous at some extents in four banks: NABIL, Nepal Investment Bank, Mega Bank and Siddhartha Bank. However, it is not in Civil Bank and Nepal Bank.

In general, the corporate sector forms CSR team as international practices for whole year CSR activities. In the sample Commercial Banks, there is not such team for CSR activities. It also indicates the least priority of the Commercial Bank on CSR activities and no mandatory of CSR. Its reflection can be found in CSR size and Percentage of Profit. In general, the Commercial Banks have at least double-digit billion Rupees profit per annum. However, their sacrifice for CSR to social cause and value creation negligible that is 0.05 percent. Thus, the Commercial Banks have negligible size and share of profit on CSR. In other words, it is ignorance of the Commercial Bank to their social responsibility.

Table 1. CSR characteristics of the Commercial Banks

Indicators	NABIL	Nepal Investment Bank	Mega Bank	Siddhartha Bank	Civil Bank	Nepal Bank
No of Years for CSR	5	3	4	2	1	1
Regularity in some years	yes	yes	yes	yes	no	no
CSR Size	41,43,094	38,04,000	0	610,000	60,000	53,00,000
% of Profit	0.04	0.14	0	0	0.013	0.18
CSR team	No	No	No	No	No	No
CSR events(Mean)	5	12	4	6	2	1
CSR disclosure	yes	yes	yes	yes	yes	yes
Establishment Year	1984	1986	2010	2002	1993	1937

Source: Audit Report of the commercial Banks, 2008-2017 and Official Websites of the Banks

5.2. CSR Trends of the Commercial Banks

CSR of the corporate is must. Literatures argue the corporate having social responsibility to the society because of ethical business as well as value creation of business. In USA and Europe countries, its trend is positively inclining. It has a good impact on the society and the sales of the corporate. How much the Commercial Banks have practiced CSR since their establishment is concerned to understand the Commercial Bank's level of ethical business. Based CSR disclosure of the Commercial Banks, CSR trend is irregular and discontinuous over nine year's data. NABIL bank has six years trend with the fluctuation. Nepal Investment Bank has also 3 years trend meanwhile other remaining Commercial Banks (Mega Bank, Siddhartha Bank, Civil Bank and Nepal Bank) has not trend. When we observe the awareness and understanding level about CSR nationally and internationally, its trend line is positively inclining. However, in the Commercial Banks, its trend line is erratic and unpredictable. Its impact is negative.

Table 2. CSR Trends of the Commercial Banks

Year	NABIL (Rs)	Nepal Investment Bank (Rs)	Mega Bank (Rs)	Siddhartha Bank (Rs)	Civil Bank (Rs)	Nepal Bank (Rs)
2008	0	28,35,000	0	0	0	0
2009	0	80,00,000	0	0	0	0
2010	0	577,000	0	0	0	0
2011	0	0	0	0	0	0
2012	115,000	0	0	0	0	00
2013	420,000	0	0	0	0	0
2014	24,25,000	0	0	0	0	0
2015	201,30,000	0	0	0	0	0
2016	250,000	0	0	0	0	53,00,000
2017	11,16,783	0	0	610,000	120,000	0

5.3. CSR Pyramids

CSR Pyramids has four major components: value creation, philanthropy, legal provision and ethical responsibility. In developed countries, they have practiced all components as social responsibility of their corporate business. In the least CSR size and its irregular practices, there is concern about CSR Pyramids to understand the structure and composition of CSR.

Whatever the Commercial Banks have conducted CSR activities, almost all the Commercial Banks have given first priority on philanthropy. NABIL and Nepal Investment Bank have given priority on value creation. Except philanthropy and value creation, the Commercial Banks have not given priority as ethical and legal compliances. Out of total CSR activities, the commercial Banks have given 25 percent priority on philanthropy and 12 percent on value creation. Thus, CSR activities have not followed international practices of CSR.

Table 3. CSR Pyramids of the Commercial Banks

CSR Pyramids	NABIL	Nepal Investment Bank	Mega Bank	Siddhartha Bank	Civil Bank	Nepal Bank
Ethical responsibility	0	0	0	0	0	0
Legal provision	0	0	0	0	0	0
Philanthropy	1	1	1	1	1	1
Value creation	1	1	0	0	0	0

Source: Audit Report of the commercial Banks, 2008-2017 and Official Websites of the Banks

5.4. CSR Size of the So Claimed CSR Bank, NABIL

This is case of NABIL. The selection of NABIL is due to the so claimed CSR first Bank and the CSR disclosure. Despite voluntarily nature of CSR, there is a query about CSR size in the percentage of NABIL's Profit. When we observe nine years' time series data of CSR and Profit of NABIL from 2008

Table 4. CSR size of the so claimed first CSR Bank, NABIL

Year	CSR (Rs)	Profit(Rs in Billion)	% CSR of Profit
2008	0	1.55	0.00
2009	0	1.63	0.00
2010	0	1.14	0.00
2011	0	1.34	0.00
2012	115,000	1.70	0.01
2013	420,000	2.22	0.02
2014	2425,000	2.33	0.10
2015	201,30,000	2.10	0.96
2016	250,000	3.62	0.01
2017	11,16,783	3.62	0.03

Source: Audit Report of the commercial Banks, 2008-2017 and Official Websites of the Banks

to 2017, NABIL has maintained 2.12 billion mean profit. However, its mean CSR is approximately 0.11 percentage sacrifice of the profit. It is very least. Because of its voluntarily and non-ethical practices, whatever size of CSR is impressive. When we observe other Commercial Banks, their situation is worse more than the CSR first bank, NABIL. It indicates no schooling and behavior of the corporate to CSR.

If we observe CSR and Profit of NABIL from 2012 to 2017, we can get positive correlation between CSR and Profit. However, if we observe negligible CSR portion of profit, its impact can be found to create value creation and business promotion of NABIL in terms of the growth of profit. Thus, CSR is valuable multiplier of profit of NABIL.

5.5. CSR Provision

CSR provision is must. In USA, European countries and India, it is mandatory to sacrifice at least 2 percentage of the corporate profit. In 2017, Microsoft company made 8 billion US\$ profit, out of which the company raised 1 billion US\$ CSR fund. It is nearly 12.5 percent of the company's profit. It is not mandatory but also ethical and value creation activities. Microsoft is motivated with the positive impact on sales and profit. In Nepal, it is voluntarily. Therefore, its impact and compliance are ineffective.

In the Commercial Banks, there is small telephone survey about CSR provision to 60 professionals. Almost all respondents have given voluntarily as reason behind small size of CSR. In addition, they hope that CSR will increase, if the provision is made mandatorily. Therefore, almost all focus on the need of CSR mandatory in the corporate law.

Table 5. CSR provision

CSR provision	NABIL	Nepal Investment Bank	Mega Bank	Siddhartha Bank	Civil Bank	Nepal Bank
Mandatory	0	0	0	0	0	0
Voluntarily	100	100	100	100	100	100
Need to Mandatory	100	100	100	100	100	100

Source: Field Survey, 2018

5.6. CSR Survey with Stakeholders

In the study, CSR survey with Stakeholders provides the stakeholder's perception about CSR situation, level, need and suggestion. The CSR survey with Stakeholders was conducted at small scale (100 respondents) in above sample banks to just understand the stakeholder's perception, understanding, satisfaction level and suggestion. The respondents were five categorical people: politician, professional, business, general customer and general people.

CSR knowledge is important to stakeholders to make effective CSR activities. If we assume all stakeholders have information and knowledge about CSR, it will be wrong. In the survey, except politicians, professionals and business people, general customer and general people have least knowledge about CSR (see its details in Table 6). May be it is due to the poor, small and irregular CSR of the Commercial Banks. Table 6 shows that except General Customer and General people, the politicians, professional and business people have some extent of knowledge about CSR activities of the Commercial Bank. However, most of all respondents have not information about CSR activities of the Commercial Bank,

although most respondents of politicians, professionals and business people have acknowledged that they are CSR stakeholders.

As stakeholders, they should have higher satisfaction level. Table 6 shows their poor satisfaction level. Almost all stakeholders have opined need of CSR and Banks should conduct CSR. Therefore, small CSR of the Commercial Banks is still insufficient to make good impression to the stakeholders.

Table 6. CSR survey with Stakeholders

Respondents	Knowledge about CSR		CSR activities of the commercial bank		if yes, its frequency	Are you stakeholder in CSR		your satisfaction level		should the Bank conduct CSR	
	Yes (%)	No (%)	Yes (%)	No (%)		Yes (%)	No (%)	Good (%)	Poor (%)	Yes (%)	No (%)
Politicians	70	30	30	70	1	60	40	30	70	100	
Professional	90	10	50	50	2	80	20	20	80	100	
Business people	60	40	30	70	3	70	30	25	75	100	
General Customer	20	80		100	0	40	60		100	100	
General People	5	95		100	0		100		100	100	

Source: Field Survey, 2018

6. CONCLUSION

Despite the strong commitment of FNCCI on effective CSR and business ethics in different public programs and voluntary obligation of CSR in Law and Policy, reality of almost the Commercial Banks is very gloomy and contradicted with the so-called practice of CSR because the practice of CSR is very irregular, voluntary, small and poor. Therefore, its outcomes cannot be accounted at significant level in social interest and business promotion. However, they have positive impact on the community for improving the relationship between the corporate sector and the community. Therefore, the government should make effective policy measures related to CSR, like as Europe and USA so that the corporate sector can sacrifice their profit regularly and uniformly in accordance with the CSR provision of Law and Policy. Then, the country will get significant benefit in the side of skill transformation, social security, community development and environment protection. Otherwise, the Commercial Banks will be a hot issue in future for the community and the civil society conducting movement for CSR.

What Can Organizations Do to Combat Human Trafficking?

5

Laura Dryjanska

Biola University, USA

INTRODUCTION

Human trafficking has become a relatively common term used by the media, policy makers, and scholars. In particular, criminologists and sociologists have been interested in this social issue for decades, but numerous other disciplines such as psychology (especially in the area of dealing with the complex trauma that victims undergo), economics, political science and others have been tackling the issue. However, it appears as a still relatively new topic for industrial-organizational psychologists.

The objectives of this chapter consist of discussing the most influential definitions of human trafficking and presenting the latest statistics that articulate diverse forms of this crime, in order to delineate specific ways in which the organization managers can actively participate in efforts to combat it.

This chapter discusses human trafficking in the context of organization management and corporate social responsibility. On the one hand, workplaces may directly or indirectly benefit from slave labor; on the other hand, there is a potential for some less obvious links with sex trafficking, especially when it comes to individual workers and some unspoken rules of organizational culture. This creates a number of possibilities for a workplace to actively engage in fighting human trafficking, especially in the areas of prevention and partnership. Annually updated Trafficking in Persons Report consistently pays more attention to the role of organizations. The latest edition draws the readers' attention to using financial transactions to uncover human trafficking and features a number of tools developed by inter-governmental organizations.

Efforts to combat human trafficking should start with corporate leadership taking a stand. Sensitive leaders encourage employee training programs that empower workers to report suspicious activities to management and law enforcement. Once there is a level of basic knowledge in the company, some entities can be open to hosting corporate volunteer days or launching an initiative that personally engages employees in the fight against human trafficking, in cooperation with local anti-trafficking organizations in the community to cater to the greatest local needs. Simple acts such as delivering meals, hosting a clothing drive, or creating amenity kits for survivors can make a difference, while at the same time integrating employees. In some cases, employee volunteers may be able to provide a skillset that helps further the work of a local anti-trafficking organization. Such efforts should be promoted and recognized by the leaders. Aside from educating employees, many organizations can further spread awareness on the issue of human trafficking by educating their customers. For example, the travel and tourism industry can distribute resources for customers to spot and report trafficking incidents on travel itineraries. Regardless of the type of organization, each and every one should be committed to slavery-free supply chains. A good start is to have a requirement for every supplier and vendor to sign a contract saying that they will not knowingly engage in labor and/or sex trafficking. Moreover, multiple organizations have financial resources that permit them to engage in anti-trafficking philanthropy. Companies can create

DOI: 10.4018/978-1-7998-3473-1.ch063

employee campaign funds specifically dedicated to this cause; service organizations, corporate and family foundations also provide much-needed funding for anti-trafficking organizations.

While the above actions resonate with many corporate managers, this chapter intends to provide a systemic, theoretical lenses to present and assess the ways in which organizations can wisely engage in the global and local fight against human trafficking.

BACKGROUND

The year 2000 appears as a pivotal moment for defining human trafficking – it is in this year when the U.S. Congress and a few months later the United Nations have issued official descriptions of this crime. The specific U.S. law is the Trafficking Victims Protection Act (2000), which singles out two “severe forms of trafficking in persons”: (1) sex trafficking in which a commercial sex act is induced by force, fraud, or coercion, or in which the person induced to perform such act has not attained 18 years of age; and (2) the recruitment, harboring, transportation, provision, or obtaining of a person for labor or services, through the use of force, fraud, or coercion for the purpose of subjection to involuntary servitude, peonage, debt bondage, or slavery (Section 103, 8). The United Nations’ definitions are known as the Palermo Protocol and specifically state that “(a) “Trafficking in persons” shall mean the recruitment, transportation, transfer, harboring or receipt of persons, by means of the threat or use of force or other forms of coercion, of abduction, of fraud, of deception, of the abuse of power or of a position of vulnerability or of the giving or receiving of payments or benefits to achieve the consent of a person having control over another person, for the purpose of exploitation. Exploitation shall include, at a minimum, the exploitation of the prostitution of others or other forms of sexual exploitation, forced labor or services, slavery or practices similar to slavery, servitude or the removal of organs; (b) The consent of a victim of trafficking in persons to the intended exploitation set forth in subparagraph (a) of this article shall be irrelevant where any of the means set forth in subparagraph (a) have been used; (c) The recruitment, transportation, transfer, harboring or receipt of a child for the purpose of exploitation shall be considered “trafficking in persons” even if this does not involve any of the means set forth in subparagraph (a) of this article; (d) “Child” shall mean any person under eighteen years of age.

The Palermo Protocol definitions, although commonly quoted, have been criticized by scholars for the tautological use of the term “exploitation” (Weitzer, 2014) and the difficulty to apply it in empirical studies (Skilbrei & Tveit, 2008). In a similar fashion to the U.S. Congress, it defines human trafficking as “the recruitment, transportation, transfer, harboring or receipt of persons, by means of the threat or use of force or other forms of coercion, of abduction, of fraud, of deception, of the abuse of power or of a position of vulnerability or of the giving or receiving of payments or benefits to achieve the consent of a person having control over another person, for the purpose of exploitation” (U.N. General Assembly, 2000: 2). Nevertheless, the Palermo Protocol may appear useful as it singles out some specific purposes of exploitation, namely: prostitution of others or other forms of sexual exploitation, forced labor or services, slavery or practices similar to slavery, servitude or the removal of organs. The type of exploitation not explicitly enlisted in Palermo Protocol is for example child marriage, considered by many researchers as a practice similar to slavery (Raj, Jackson, & Dunham, 2018). In fact, the International Labor Organization has decided to include victims of this phenomenon in the latest statistics concerning the worldwide number of victims of human trafficking.

This brings up the burning question: how many people in the world are victims of this crime? There is no easy and precise reply, as already evident from the blurriness and plurality of definitions. The most

Figure 1. Percentage distribution of victims of modern slavery, by sex and category. Source: International Labor Organization, Walk Free Foundation, & International Organization for Migration (2017).

recent estimates (International Labor Organization, Walk Free Foundation, & International Organization for Migration, 2017) state that on any given day in 2016 there were 40,293,000 persons in servitude, of whom approximately 16 million in forced nonsexual labor exploitation, 5 million in forced sexual exploitation, 4 million in state-imposed forced labor, and 15 million in forced marriages. Figure 1 shows the percentage distribution of victims of modern slavery, by sex and category.

Trafficking and forced labor play a major role in the economies of many countries (Peksen, Blanton, & Blanton, 2017). From the point of view of organization management, the form of modern slavery that has the highest potential to be somehow related to or influence corporate activities is labor trafficking. Although it includes labor exploitation (when employers deny workers their rights under federal and state labor law, such as the right to fair compensation, working conditions, and working hours), the two phenomena are not synonymous. According to Farrell et al. (2018), the exploitation has to occur through the use of force, fraud or coercion to be considered labor trafficking. Experiences of physical violence, document fraud or withholding documents, and isolation, restrictive movement, and communications can result in pervasive health concerns. This has led some researchers (De Vries & Farrell, 2017) to consider labor trafficking victimization as a form of polyvictimization. Individuals are much more vulnerable if they are immigrants, which often means that they do not speak the language of the destination country and do not understand the culture, especially their rights and obligations of their employers. Thus, one cannot ignore the fact that labor trafficking is often related to migrant worker abuse. There is a fine line between diverse forms of abuse of vulnerability of migrant workers and its escalation into trafficking situations. Chuang (2017) identifies foreign labor recruitment as one of the areas related to labor trafficking. She believes that the recruitment market often “turns migrants into debtors, leaving them vulnerable to a wide range of exploitative practices by unscrupulous recruiters” (Chuang, 2017: 149). Such practices include exorbitant recruitment fees, contract switching, and prolonged abusive

treatment by the employers. Outsourcing of labor migration management to recruiters usually helps fuel market-oriented governance that prioritizes private profit interests over migrant welfare. According to Bhavnani and Schneider (2015), most trafficking occurs within a person's own country or region, and often for non-sexual forms of labor. Domestic trafficking usually affects men in the developing countries, who may be forced into debt-slavery or hard labor by dictatorial regimes. Additionally, children are trafficked to become soldiers (e.g. Uganda), domestic servants (Philippines; Pakistan), beggars, or laborers on plantations and in factories.

HOW TO FIGHT HUMAN TRAFFICKING?

How do organizations combat human trafficking?

When the official definitions were introduced in 2000, the U.S. government has also established norms around three Ps: Prosecution of traffickers, Protection of victims, and Prevention of the offense. Then, in 2009, a fourth P was added, emphasizing Partnerships between governments, multilateral organizations, non-governmental organizations (NGOs), and the private sector. Prosecution of traffickers should be certain, swift, and proportionate to the gravity of the offence to be an effective deterrent. Unfortunately, in relation to the reported number of persons trafficked, the number of successful prosecutions is an abysmal few (Winterdyk, 2018). An organization may be in a position to provide proofs in anti-trafficking cases (documentation or witnesses' testimonies), especially in cases of labor trafficking. Although this implies time and thus resources, the corporate social responsibility requires maximum collaboration with the authorities in the efforts to prosecute traffickers.

Strategies to protect victims include 3 R's (Rescue, Rehabilitation, and Reintegration) and organizations can play a vital role in an initial stage by developing the ability to identify potential human trafficking victims both among its employees and the people that they encounter, using proactive identification methods. Since virtually anyone can come across a potential human trafficking victim, it is crucial to know the signs of this hidden crime, and to raise awareness among workers concerning for example the anti-trafficking hotlines that one should contact in case of a suspicion. If an organization is in a position to temporarily offer protection to a human trafficking victim without jeopardizing anyone's safety, it should consider this possibility, in close collaboration with authorities. While most organizations will not be involved in the rescue and rehabilitation of survivors (this delicate and possibly dangerous process should be left to professional agencies), they can play a role in their reintegration, for example by offering employment to formerly trafficked individuals who have undergone the rehabilitation process.

According to Steiner et al. (2018), most prevention efforts can be categorized into three different types of models: a law enforcement or criminal justice model, a migrants' rights model (main focus on labor trafficking), and a human rights-focused model (main focus on sex trafficking). The first model concentrates on criminalizing human trafficking seen primarily as an issue of national and international security, with the main focus on efforts to prosecute traffickers. The second model emphasizes the perspective of an individual immigrant worker who should be protected from exploitation, ensuring the enforcement of proper rules and regulations at workplaces, as well as offering individuals information concerning their rights. In a similar vein, the third model also considers the victims' rights (specifically, human rights), but tends to amplify the highly emotional public outcry regarding trafficking of women and girls, echoing the outrage of the historical response to white slavery. On its own, none of these models can be effective to counteract such complex crime as human trafficking; the key is a combination of efforts on various levels, targeting all types of trafficking.

For all of the prevention models discussed above, information about trafficking aimed at law enforcement officers, potential and current labor trafficking victims, and women and girls trapped in prostitution is essential. Thus, raising awareness also constitutes a crucial part of prevention. Various materials are being printed and disseminated online by public and private organizations, informing potential victims of their rights and offering possible ways out to current victims. For example, since 2015, the Orange County Transportation Authority (OCTA) in California has trained hundreds of coach operators to identify and help victims and has used its buses as traveling billboards with Be the One campaign (see Figure 2).

Figure 2. Local transportation organization helps increase awareness about human trafficking in Orange County, California. The photograph features an Italian Rotarian volunteer, Roberto Giua who attends the meeting of the Orange County Human Trafficking Task Force on January 25, 2018. Source: photo by author.

Moreover, websites of many organizations now feature information about human trafficking; in fact, according to Martin et al. (2017), almost a third of Fortune 500 companies mention human trafficking on their websites. Workers who travel may be exposed or even lured into sex tourism; they should be informed about its links with modern slavery, especially in case of commercial sexual exploitation of children.

Finally, partnership to combat human trafficking refers to collaboration among anti-domestic violence organizations, attorneys, victim assistance providers, health services providers, and local law enforcement to provide combined services to achieve goals and objectives beyond any individual organization's capacity, in line with the coalition model (Kim et al., 2018). An example of partnership is the group of large international corporations (including, among others, Coca-Cola Company, ExxonMobil, Ford, Microsoft, and LexisNexis) forming the Global Business Coalition Against Human Trafficking. These companies are working to combat human trafficking by teaching employees to notice indicators of possible trafficking victims.

More recent scholarship emphasizes the need for transformative partnerships, with four common denominators (Lagon, 2015): market – accounting for the supply of trafficking victims (e.g., children detached from family and regular and irregular migrants) and demand (for cheap products, cheap labor, and purchased sex); metrics – empirical bias for choosing interventions and measuring progress; matching missions based on aligned goals; and motives or sound intent that goes beyond window-dressing corporate social responsibility or discrete philanthropy without addressing human trafficking in its business operations or supply chains. According to Martin et al. (2017), by setting up a company policy against human trafficking, top management makes it clear to consumers, employees, investors and business partners that this crime is not tolerated. It is essential to keep an up-to-date anti-trafficking policy, along with monitoring, risk assessment and stringent remediation practice. Effective management of a supply chain requires full understanding of its activities, including awareness of where key suppliers are located and the work environment in those places. Organization executives need an action plan to pay special attention to industries and places where there is substantial risk for trafficking. A supply chain audit can be an integral component in monitoring and enforcing anti-trafficking policies (Gold et al., 2015). A supply chain audit can help detect worker exploitation and other violations of anti-trafficking policies; the auditors should pay attention to the red flags identified by the U.S. Department of State (2015) including: living with employer, poor living conditions, multiple people in cramped space, inability to speak to an individual alone, answers that appear to be scripted and rehearsed, employer holding identity documents, signs of physical abuse, submissive or fearful demeanor of a worker, employees who are unpaid or paid very little, and presence of workers under 18 and in prostitution. Some strategic choices that organizations can make in terms of their corporate social responsibility concern taking transparency more literally by providing greater levels of detail about the exact provenance of their products and making specific data available as a public good (New, 2015). In their study of corporate disclosures in the apparel industry, Ma et al. (2015) concluded that suppliers, especially in China, are using increasingly advanced techniques to cheat code of conduct inspectors and further changes need to be implemented to help resolve this issue.

Specific corporate efforts to combat human trafficking are not optional anymore in many countries. The 2015 amendments to the Federal Acquisition Regulation, require United States government contractors to actively root out human trafficking throughout their supply chains. In addition, various state and international disclosure laws require companies to disclose to consumers what efforts (if any) they make in that regard. The U.K. Modern Slavery Act of 2015 requires that every organization with annual income in excess of £36m carrying on a business in the U.K. must produce a slavery and human trafficking statement for each financial year. The French Supply Chain Vigilance Law requires French parent companies with at least five thousand employees to identify and avoid adverse human rights and environmental impacts of their own activities and the activities of enterprises they control or with whom they have an established commercial relationship. Phillips et al. (2016) found that 55 new pieces of national legislation imposing mandatory requirements onto companies to disclose information about

labor issues in their supply chains have been passed since 2009. This implies regulation of efforts to combat human trafficking on a corporate level. However, LeBaron and Rühmkorf (2017: 29) conclude that “after nearly two decades of activist pressure on governments to strengthen systems and initiatives to detect and address forced labor and slavery, the business of forced labor continues to be insufficiently regulated.” Their research on domestic politics of corporate accountability legislation has elucidated the role of industry actors in creating and maintaining the governance gaps that allow labor abuse to thrive, as they have identified private, industry-led mechanisms and sought to deflect alternative regulatory tools with greater stringency. McGrath and Mieres (2017) believe that labor regulation, the international trade regime, worker organizing models, migration policy, and a host of other political-economic and social factors structure the conditions within which the human trafficking supply chain nexus is situated.

In relation to socially responsible organization management aimed at combating human trafficking, Chuang (2017) proposes a term *philanthrocapitalists*. Philanthrocapitalists use their business skills to tackle social problems such as human trafficking. Corporations are positioned as crucial agents of change by engaging in more ethical recruitment practices and better supply chain management. “Anti-trafficking-focused philanthropies have even combined forces to create an impact investment fund (with aspirations of reaching US\$ one hundred million by 2020)—that aims “to bring much-needed strategic focus and financial resources to the fight against modern slavery” (Chuang, 2017: 150). Certainly, not every organization can aspire to become philanthrocapitalists. However, many workplaces can engage in some of the similar efforts, especially if they use recruitment agencies to hire migrant workers and choose an agency that abides by ethical standards and safeguards against labor trafficking.

As shown by Azad (2018) on the specific case of migrant workers from Bangladesh, fair and transparent recruitment has the potential to ensure better working and living conditions for them. In this particular situation, the legal and ideal scenario is that of a recruitment actor collecting vacancy information in the destination and then recruiting workers from a database of workers in Bangladesh who have already registered to migrate overseas, or an employer in the destination hiring services of an agency to recruit required workers. Each step of this process should be in line with the existing regulatory bodies. Unfortunately, in practice, according to Azad (2018), the recruitment on both sides is a mix of both legal and illegal practices. It is quite common that an unlicensed and unauthorized broker buys a work visa from the employer and sells it to the worker in Bangladesh, often making a high profit. As proposed by the International Recruitment Integrity System (Wickramasekara & Baruah, 2017), the recruitment should be fair to all parties involved, including: a) the employers – by hiring the right person with the right competencies for the job without fear of being duped by unscrupulous intermediaries; b) the migrant workers – by finding suitable and legal employment without paying for the right to work, having their passport confiscated, or becoming a victim of labor trafficking or forced labor; c) the recruiters – by fair competition for professional recruiters and employment agents who practice honest, transparent, and fair recruitment. The focus on recruitment is a preventive measure to reduce the future exploitative experiences of the migrant workers. Special attention should be placed on ensuring that an organization does not benefit from child slavery, in particular in the context of labor taking place in developing countries.

Nevertheless, there is a lot of skepticism concerning the organization’s willingness and actual capacity to combat human trafficking. According to Limoncelli (2017: 122), “relying on companies’ voluntary initiatives usually produces only modest and uneven improvements of working conditions and labor rights along global supply chains.” She believes that in reference to this point, Brazil’s model of placement of companies on the “dirty list” coupled with governmental inspections and sanctions (such as bank-lending penalties, the freezing of assets, and the denial of government subsidies) has proven quite efficient.

SOLUTIONS AND RECOMMENDATIONS

According to Patterson and Zhuo (2018), the United States has taken the lead among the advanced nations in promoting awareness of the problem and encouraging countries to take action against it, with its State Department's annual Trafficking in Persons Report and its Labor Department's Worst Cases of Child Labor Report. Moreover, the European Union and the major global institutions, most notably the United Nations (U.N.), have been active in documenting and promoting similar programs against the problem. In particular, the U.N. has formally adopted the eradication of trafficking and forced labor as one of the major goals of the 2030 agenda for sustainable development.

In their study with advocates from the field of human trafficking across the globe (Steiner et al., 2018), the interviewees highlighted the importance of anti-human trafficking organizations engaging in work utilizing individual, collaborative and societal/public policy approaches while understanding the way in which the culture/country context impacts socioecological approaches.

Therefore, besides international and national efforts, there is a lot that can be done to combat human trafficking on an institutional and individual levels. This is where organizational management and corporate social responsibility sensitive to this issue comes into play.

While virtually any organization can identify and implement a specific action to combat human trafficking (for example by raising awareness among its employees), there is a growing number of entities whose mission and vision are centered on this issue. Bain (2017) enlists a number of entrepreneurs focused on addressing human trafficking, whom she considers as the new wave of changemakers.

Numerous organizations concentrate on primarily assisting human trafficking survivors. Formerly known as Made By Survivors, now rebranded as Her Future Coalition is a social enterprise based in the U.S. It developed a business model to ensure that trafficking survivors were economically empowered as entrepreneurs themselves, minimizing the risk of them being trafficked again. The organization works with other suppliers and partners to sell products made by the survivor-entrepreneurs in Nepal and India in the U.S. and beyond, while expanding shelter services, education opportunities, and employment for the victims. Numerous other organizations engage in similar activities on a local, national, and global level. A business unrelated to human trafficking can identify a partner organization like Her Future Coalition, supporting its efforts by purchasing products made by survivors, for instance to use them as gifts for its employees or clients.

Another way to combat human trafficking as an entrepreneur is to tackle global supply chains and a specific business sector, for example fashion. A California-based social enterprise called Remake has created and runs a "storytelling platform" to foster humanity within fashion markets. It is a way to foster a social and consumer movement around stopping labor trafficking within fashion supply chains. At times, the scope of similar efforts by a single organization may be broader, including various business sectors in a certain region. For example, the Mekong Club is an organization in Hong Kong that supports and assists the private sector in the fight against human trafficking in Asia by establishing specific networking groups that offer business expertise in supply chains and operations.

Companies that specialize in technology step into the fight against human trafficking in the area of mapping, applying cutting-edge aspects of geospatial analysis and using investigative modeling in big data analytics. An example of an organization that pioneered this type of efforts is Deloitte. Combating human trafficking is interwoven with a number of services that the company performs, including consulting the Deloitte's Global Security and Justice practice. The company helps clients make globally informed and locally relevant choices about border management, law enforcement, aviation, and immigration, with the overarching goal of helping clients solve security-related challenges, including human trafficking.

Deloitte has also been successful in partnering with academia and activists, by not only co-sponsoring a networking event (Freedom from Slavery Forum organized by Free the Slaves), but also having its own employees share the acquired technological know-how with 38 leaders from 36 organizations across the globe, and thus becoming an integral part of the forum (see Figure 3).

Figure 3. The third Freedom from Slavery Forum at Stanford University. The photograph features the participants on October 6, 2017. Source: photo by author.

Some noteworthy anti-trafficking efforts have been launched by well-established service organizations, such as Rotary, with a specific dedicated international group of volunteers, Rotarian Action Group Against Slavery. In this case, the existing structure of such large organizations with well-established funding mechanisms and presence across the globe, facilitates raising awareness both among members and the general public, as well as financing specific projects aimed at eradication of human trafficking.

FUTURE RESEARCH DIRECTIONS

When it comes to human trafficking, obtaining ever more reliable empirical data is necessary for shaping meaningful policy discourse and the development of effective countermeasures (Zhang et al., 2014). A

considerable further research is required to understand precisely how far and in what ways the strategic mobilization of private governance might be impacting the stringency of reflexive regulation to bolster labor standards, and to discuss the displacement effects that may be occurring as private actors seek to undercut efforts to strengthen public governance of labor in global supply chains (LeBaron & Rühmkorf, 2017). McGrath and Mieres (2017) identify as an important future research direction the task of mapping the emerging and rapidly growing field of activity around the human trafficking supply chain nexus in order to set the context for detailed qualitative analysis.

CONCLUSION

As stated by Philips (2017), creating organizations to fight for social and environmental justice should receive at least as much attention in management research as creating more effective and profitable organizations. Human trafficking is a diversified and multi-faceted criminal industry that generates considerable revenue. It may be related to a number of areas of activity of an organization, in particular in terms of the supply chain management and migrant workers. Active efforts to combat human trafficking should be reflected in the enactment of corporate social responsibility of organizations. Even on the level of a company's board of directors (responsible for determining the material issues that the company should be reporting on), increasing attention is being paid to anti-trafficking actions. According to Eccles (2017), in certain industries such as agriculture, food products, and manufacturing, failure to eliminate human trafficking in their supply chain can damage the long-term viability of the company. Consumer reaction to modern slavery abuses can damage the company's brand (and stock price), have negative effects on the morale of its employees, and make it difficult to attract new ones.

As shown in this chapter, the private sector has launched numerous inventive approaches to fight human trafficking, including some pioneering models in a wide range of sectors. Technology and data analysis tools can be helpful to follow transactions and identify potential traffickers, which is especially significant in the financial sector. Supporting research and collaborative efforts between multiple external stakeholders, including public-private partnerships, leads to a better understanding of how technology is used to facilitate human trafficking. In the transportation sector, both individual users and employees can make a difference through raising awareness, enhancing prevention, and reporting possible cases of trafficking. This applies also to the hospitality sector, where in addition entrepreneurial thinking and innovation can provide support for survivors of trafficking by offering temporary refuge. Examples are numerous, but certainly more can and should be done by organizations to combat human trafficking as a way to enact the corporate social responsibility.

KEY TERMS AND DEFINITIONS

Corporate Social Responsibility: Taking into account the organization’s social, economic and environmental impact, and consideration of human rights; conducting business in an ethical way.

Human Trafficking: Modern-day slavery that involves the use of force, fraud, or coercion to obtain some type of labor or commercial sex act; also referred to as trafficking in persons (TIP) or modern slavery.

Palermo Protocol: Protocol to Prevent, Suppress and Punish Trafficking in Persons, especially Women and Children adopted by the General Assembly of the United Nations in 2000.

Philanthrocapitalists: New generation of philanthropists who (unlike earlier generations of philanthropists, who focused on funding third party initiatives) are creating and actively managing their own ventures, using their access to the global elite to assume a direct role in global governance; crucial agents in anti-trafficking efforts.

Supply Chain Management: All activities related to the management of the organization’s supply chain (including product development, sourcing, production, and logistics, as well as the information systems needed to coordinate them), aimed at maximizing customer value and achieving a sustainable competitive advantage.

Trafficking Victims Protection Act: Introduced in 2000 by the Congress of the United States, the first comprehensive federal law to address trafficking in persons. The act provided a three-pronged approach that included prevention, protection, and prosecution, with the subsequent addition of partnership.

Transformative Anti-Trafficking Partnership: Partnership of various organizations aimed at helping human trafficking survivors reclaim dignity and actually reducing or abolishing the ongoing threat to potential victims. Such partnership is attentive to market forces, takes metrics seriously, has matching missions, and exhibits sound motives.

A Guide to Cracking Down Cyber–Ethical Dilemmas

Wanbil William Lee

The Computer Ethics Society, Hong Kong & Wanbil & Associates, Hong Kong

INTRODUCTION

Brutal cyberattacks continues, the exorbitant cost of damages keeps on soaring, *cyberwar* proliferates fast despite the *big spending* (in billion US dollars) on cybersecurity. This is skin to a vicious circle culminating in a chronic disease aptly called a “chronic problem of data protection” (Lee, 2019). The problem is arguably rooted in our indifference to ethics or insufficient understanding of the ethical principles and the practice of these principles, so that the ethical dimension of the problem is missed out when formulating information security policies and implementing information protection systems.

Fallacious beliefs and *relativistic arguments* exacerbate the problem; the tripartite relationship, called the “*Ethics-Law-Security Connection*”, complicates the situation. The *techno-ethical threats* prove the urgency of the problem. The *ethical ramification and challenges* reinforce that urgency.

Given that it is unrealistic to keep all threats out as threats inflicted by insiders, clients, contractors, etc. are ever-existing, eradicating the problem is desirable but doomed to be futile. Hence, mitigating by lessening the incidence of hacking or making hacking exasperate so as to minimize damages is a sensible and feasible alternative. An *ethics-based guide* underpinned by Ethical Computing was conceived. The aim of this guide is to identify ethical issues, to discover significant ethical and security ramifications, to connect the issues to the relevant theories and technologies, and to resolve the ethical dilemmas, with a 3-point precondition: Know your ethics, Shift view and understanding of risk and ethics, and Take ethics seriously. This chapter is about that guide and concludes the exposition with an illustration of some common dilemmas.

BACKGROUND

Ethical Computing

Ethical Computing is the practice of *Computer Ethics*. It aims to deal with identifying/discovering ethical issues arising from developing and using computer-based application systems and analyzing these issues to come up with balanced solutions. Its current major issues of interest include privacy, intellectual property, digital-divide, professionalism, trust, anonymity, and cyberbullying. Its methods and tools for ethical analysis include the *Ethical Matrix* and *Hexa-dimension Metric*. (Lee, 2015b and Lee, 2018a)

Computer Ethics

Ethics is the same in peace times as during the *cyberwar era*. Computer Ethics, Data Ethics, Cyberethics are terms that denote more or less the same phenomenon. While *Data Ethics* is about the ethical issues

DOI: 10.4018/978-1-7998-3473-1.ch064

involved in collecting, sharing, interpreting, synthesizing, and using data (Floridi & Taddeo, 2016), *Computer Ethics* or cyberethics is a subfield in Applied Ethics akin to Business Ethics, Technology Ethics, Medical Ethics, etc., and focuses on the *ethical issues* surrounding the computer. Following the classic definition by Moor (1985), different views of Computer Ethics appear in the literature (Johnson, 2009, for example). Computer Ethics has a wider scope and should be viewed as a dual mission (a discipline cum practice grounded in ethical principles) and a dual function (a risk as well as an anti-risk mechanism) (2014-15).

Ethical Principles

Only the common theories/principles are briefly reiterated in this chapter for illustration purposes.

Duty-based principles

- *Deontology* asserts that an action is morally right if it is done out of a sense of duty.
- *Kantian Categorical Imperative* tells us never to treat human beings merely as means to an end; always treat them as ends in themselves. A human being hence has a right not to be exploited and has a duty not to exploit another human being.

Results-based principles

- *Consequentialism* holds that an action is morally right if its consequences are beneficial or morally wrong if its consequences are harmful.
- *Utilitarianism* means that an action is morally wrong if its results are more harmful than beneficial.

Other common principles

- *Golden Rule* states that “Do unto others as you would have them do unto you” or “We should do to others what we would want others to do to us”.
- *Social Contract Theory* says that an action is morally wrong if someone’s rights are being violated or an action is good if it is carried out in accordance with moral rules that rational people would collectively accept as binding because of the resulting benefits to the community.
- *Virtue Ethics* advises us to live according to the values we cherish and care.

Note: Sometimes these principles may be in conflict; self-reflection/self-discipline helps to make a balanced decision.

The Double-Edged Sword Effect

Ethics has a dual function which is akin to a double-edged sword; it can be on the one hand an attacker – it can expose unethical consequences of an action that violates ethical principles or it may cause the wrongdoings to backfire at the ethical abusers. On the other hand, it can be a shield or protector or an anti-risk measure to defend actions which are consistent with the ethical principles. (Lee, 2014-15) For illustration, in the case of US President Nixon’s downfall, it is ethics that defeated him, not the law, and in the case of South African President Mandela’s survival, ethics plays a role in strengthening him against politico-legal suppression during his ordeal. The following episodes further enlighten this effect:

Audrie Pott, a 15-year-old school girl, was sexually assaulted by three boys aged 16 and 17 on 12 Sept 2012 after she passed out at a house party. Her attackers took photos of her half-naked body and shared these photos with classmates. Audrie became so distraught after seeing the photos that she killed herself. The three boys were arrested for sexual assault and admitted to a juvenile court for the heinous crime they committed. They were sentenced to serve between 30 and 45 days in a juvenile detention center. (The Mercury News, 2012)

Charlotte Dawson, a New Zealand-born Sydney-based TV performer and an ambassador for the Australian anti-bullying program Community Brave, was found dead after being subjected to a continuous tirade of abusive tweets. She dug her own grave, as a critic put it: she “has made a career of slagging off all and sundry and using her broadcasting power to bully others, calling critics bogans (low-class persons) and scraggs (a lean, meagre person, an animal)”. Here is an example of those abusive tweets: Tanya Heti, a Melbourne woman, tweeted “on behalf of NZ we would like you (Dawson) to please go hang yourself”. (The Sydney Morning Herald, 2014).

Foolish Mum: Mrs Clenston, a senior manager of a multinational bank and extremely cautious about privacy. So she used her daughter’s email address to send hate letters complaining about Mr Yuile (a neighbour) to Mr King (Yuile’s boss). King forwarded the email to Yuile.

- Yuile googled in and found “Sze-Man Clenston” on the website of one of Hong Kong’s famed schools. Yuile suspected that the complaint could have been raised by Clenston. But Clenston refused to admit it and claimed that Sze-Man was not her daughter.
- Yuile sent a copy of the hate letter to the school principal, and Sze-Man was reprimanded. The news soon spread around the whole school. But Clenston was still adamant despite Sze-Man’s innocent punishment.
- One day, another neighbour, Mrs Llewyn accidentally bumped into Sze-Man’s Facebook account and discovered a family photo showing clearly Mr & Mrs Clenston, Sze-Man, and brother holidaying on a beach somewhere. So, Mrs Clenston got no room to escape.
- Upon Yuile’s counter-complaint, Mrs Clenston lost her job, and Sze-Man left her school as a result of complaints from other students and their parents. (Lee, 2014-15)

Stupid Dad: Mr Que, a local politician, failed in the last district election and now planned for a comeback. Thinking that it would project a younger image, he uploaded his son’s photo instead of his own, in a Facebook account he set up to recruit followers and to solicit support. The hit rate was as well as expected but the younger Que was recognized as the son of a failed politician, and consequently suffered all sorts of ridicule among his friends and schoolmates! (Lee, 2014-15)

The Knowledge Effect

An exploratory study was conducted in a classroom setting and the subjects were senior Computer Science undergraduate students. The aim was to test the hypothesis that the knowledge of ethics has an effect of guiding the students to the ethical use of the computer. The result of the survey indicated that 8% of the students claimed at the start of the course that they were aware of Computer Ethics but not certain if they used the computer ethically, compared with 72% who claimed at the end of the course that they understood ethics and would use the computer ethically, and the remaining 28% (post-course population) claimed no change for various reasons. Overall, knowledge of ethics has a remarkable impact. It is noteworthy, however, that ethics has no impact on 21% (post-course population) who claimed

that understanding ethics did not change how they would use the computer (ethical or unethical). The empirical data is consistent over the seven consecutive years ($p > .05$). The conclusion testifies to this effect. (Lee & Chan, 2008)

Methods and Tools of Ethical Analysis

There are a number of methods and tools developed and applied over the years. The classic informal guidelines or tests and menu-driven linear checklists can be found in Kallman & Grillo (1996). These classical methods are either common-sense based or have embedded some basic ethical theories, and are found generally to be clumsy to use or lacking vigor. Introduced and described in this chapter are the relatively new Ethical Matrix and Hexa-Dimension Metric.

Ethical Matrix

This is a tool recently adapted from food and agriculture for ethical analysis in the IT context. The columns of the matrix correspond to “values” held by stakeholders with respect to ethical principles, and the rows correspond to the stakeholders or interest groups. The number of columns and rows may vary as required. The cells contain the concerns (the main criterion that should be met) of the stakeholders with respect to the value held (by the stakeholders) or a particular ethical principle.

Hexa-dimension Metric

This is a measurement instrument initially conceived as a checklist for decision making in technology-driven and information-intensive organizations. Its aim is to measure the values held by the stakeholders and to arrive at a balanced solution. The metric comprises six attributes that measure the efficiency (requirements): financial viability (a justifiable return on that the investment), technical effectiveness (an optimal utilization of the technologies acquired), legal validity (consistency with corporate rules and regulations and the law in force), ethical acceptability (consistency with corporate code of practice and/or the generally acceptable ethical principles) and social desirability (safety of the huge amount of data consumed and generated by the technology, and ecological sustainability (environmental protection since running the technologies consumes a lot of natural resources (electricity, water, paper, etc.), and generates air, noise pollution) (Lee, 2018b).

Techno-Ethical Threats

Arguably, abusing or not abusing the technology depends on the users’ sense of morality. Such a sense is influenced by many factors, the major amongst which is the users’ understanding of the ethical principles. Using the technology in contradiction to ethical principles constitutes a different type of risk, a techno-ethical risk or simply *ethical risk*. To illustrate, a common episode (the *Splitting Loyalty Dilemma*) is used, which is about taking home from work a USB containing corporate data for personal convenience. Doing so runs the risk of breaching privacy or undermining confidentiality. In this case, the person who takes home an un-encrypted USB in which confidential data are stored is a threat, taking home a USB is a vulnerability, and the action is a violation of data privacy, thus a risk. This risk is related partly to technology (the USB) and partly to people (both the perpetrator and the victims), and is, therefore, a techno-ethical risk. Figure 1 below depicts this phenomenon.

Figure 1.

To amplify the notion, newer threats are found to accompany new convenience and enjoyment that the modern disruptive technologies provide. It is no imagination that after our bank account number was exposed to a stranger by accident or as a result of carelessness, trusting the online bank account we log into to be true may turn out to be a forgery! This is an incidence of threats related to the Internet of Bank Accounts (IoBA). This clearly shows not only the proliferation and ubiquity of techno-threats but also insidious techno-ethical threats to personal privacy and security. IoBA inherits all the IoT related threats, and also those of Cloud Computing because IoT devices are often connected via the cloud.

It is of interest to note why IoT is attractive to hackers. IoT connects not only a huge number of devices but also numerous data points; IoT requires users to submit personal information, including name, age, address, phone numbers, and even social media accounts; the labour of stealing data or corrupting the connected devices is not overly toiling and the harvest could be a bonanza. The scavengers can net invaluable information in a single hit. Since bank accounts are closely connected, hacking into bank systems is not only easy and convenient but also lucrative.

Threats directly related to IoT include personal data leaking, denial of service, device- and application-related, for example, the hidden cameras in billboards that track the demographics of passersby who stopped to read the advertisement (*Wikipedia*), to name a few.

There are also IoT related threats arising out of the Cloud, and in connection with AI and Bog Data. IoT users more than often deposit their data on the cloud to be used instantly or in the future and may be vulnerable to threats, for example, cloud vendors could sell the users' confidential data with the ramification of personal privacy invasion and data ownership dispute. AI-driven home automation hubs,

smart locks, smartwatches, gadgets that we either keep at home, carry or even wear around, automobile navigation and infotainment systems, advanced medical devices, and automated teller machines lead to numerous threats, the common ones being Hijacked Devices Sending Spam Emails, Hijacked Devices Conscripted Into Botnets, Home Intrusions, and Remote Vehicle Hijacking” (*IoT For All*).

Ethical Ramifications and Challenges – a Few Examples

Self-Driving Cars (The Globe and Mail, 2018)

The situation here is akin to the choice being ‘delegated’ to the robot driver to decide who is going to be harmed and who’s not. This choice poses legal and ethical issues in the event of an accident:

- Where and with whom should the responsibility lie?
- What right do the pedestrians, passengers, owners of the damaged properties, etc have?
- Who should be prosecuted for the damages?
 - The driver? But the driver is not a human. Is there a law to sue a machine that is programmed to drive? Law always moves much more slowly than the event. So, there is no law yet.
 - The human programmer? The programmer who merely carries out the job according to the specs may be covered by the employer and shielded under the principle of deontology.
 - The manufacturers of the autonomous car including the robot driver? The manufacturers tend to brush aside the associated moral issues.

Autonomous Weapons (ABC News, 2018)

Like the episode with the self-driving cars, the decision is given to a machine: who should live and who should die. Given the killer robot is programmed to “kill anything moving”, any moving object – be it an armed foe or an innocent civilian, or a soldier dressed as a civilian, or a civilian dressed in uniform – will be shot. Despite the claim that “a ban [on autonomous weapons] would be impossible to enforce”, the “wrong guy” might be killed. Then,

- Who should be held responsible for the action executed by the killer robots?
- The politicians?
- The military user?
- The software company?
- Or the engineers and scientists who design and implement the autonomous arsenal?

Criminal Justice System (ProPublica, 2016)

The Criminal Justice System (CJS) is a set of risk assessment algorithms for making judgements of an ex-prisoner’s probability of re-committing a crime right after having been released. ProPublica, an American nonprofit investigative journalism organization, discovered built-in *systematic bias* in the CJS, and reported the finding. The finding reveals that the system underestimates the threat from white defendants while overestimates the threat from black defendants with the result that white defendants are given leaner sentences than black defendants. Also, the system makes mistakes about half of the time,

and the provider of the system admits when asked, that of the 137 factors included in the assessment, race is not one of them. This raises numerous ethical and legal issues and some of them are

- Is AI to be blamed for the mistakes made in the criminal justice software?
- The analyst/programmer?
- The software provider?

The Tripartite Ethics-Law-Security Connection

Ethics is related to security. First, violating ethical principles is a risk. That risk, when realized, for example, cyberbullying, reputation-distortion, falsification of identity, and so on, would lead to undesirable financial and criminal consequences. Second, security problems, be they technical or non-technical, are rooted in human errors which can be intentional or unintentional; some of us would make intentional errors out of various reasons ranging from fun or greed but none of us is immune to unintentional errors. Nonetheless, wherever and whenever is there vulnerability (mainly due to the human element in the system), risk (adversary consequences) will result wherever or whenever a threat (a human error) is actually carried out. Making an error purposefully is a violation of ethics and would lead to security concerns.

Ethics is normative and is concerned with what matters morally, things being good or bad, and actions being right or wrong while the law is positive and is about making a judgment based on fact being true or false according to a set of legislated rules and regulations. Ethics and law intertwine and ethics can be said to be a driving force behind the law. A case in point is the Donald Tsang episode (Tsang was Ex-Chief Executive of Hong Kong Special Administrative Region when on trial for infringing his official duty). The judge instructed the jury during the hearing, “This is a legal case, not a moral case”. The defence counsel, when pleading for a suspended sentence and a short prison term, asked the judge to take into account an absence of “morally questionable motive” in this case, and to consider “heavier sentence if motives morally questionable” (South China Morning Post, 2017). This case shows that ethics and law seem separate, yet linked.

Further, in cyberspace, as in the physical world, security relies on trust and in turn, privacy. That is, privacy is breached if the trust is lost, and ethics is not respected and the law is broken. This is reflective of a common course of action: we would not trust or disclose anything confidential to those who are not seen to respect privacy; we would trust our security in a protecting agent who would act according to ethical principles. Hence, there is no security if there is no trust, and there is no trust if there is no privacy. This firmly establishes the ethics-law-security connection (see Figure 1). [It is interesting to note of a surprising result in a recent case where ethics contributes to a regain of trust: Zuckerberg responded seemingly courageously by admitting mistakes and apologizing in the grilling sessions in the US congress allegedly won him trust, thus contributing to Facebook’s stock performance (a rise in stock price). (ComputerWeekly, 2018)].

Fallacious Beliefs

What is legal isn’t necessarily ethical. For argument sake, dismissing an employee who does not perform as expected can be legal and ethical; copying proprietary software as a backup, even when the agreement specifically prohibits copying for any purpose, can be ethical but not legal; distributing mailing lists without permission of the people on the lists can be unethical but legal; and pirating copyrighted software

or planting virus in someone's computer is certainly unethical and illegal. The antinomy implied by these four states of the ethics-law relationship clearly shows that fallacious beliefs are untenable. (Lee, 2014-15)

Relativistic Arguments

“What is right for you may not be right for me” is the idea of popular belief and is often heard when people argue for or defend their actions. This idea stems from the ethical theory of relativism. A relativistic argument is problematic since relativism tends to be self-contradictory; relativism cannot by itself tell us ‘right’ or ‘wrong’. Specifically, it doesn’t tell us whether what Tom does is right or wrong. Suppose what Tom does is wrong then what Dick does is also wrong. ‘If Tom can do it, then Dick can do it’ is a relativistic argument and doesn’t help to judge Tom’s action or that of Dick. (Lee, 2014-15)

Cyberwar

Cyberwar is a term initially coined to denote inter-state conflicts such as espionage campaigns launched by hackers from one country targeting firms of another country. It refers to cyberattacks at different levels and scales, ranging from individual victimization to nation-to-nation confrontation. It is interesting to note that the term *infowar* (information warfare) had appeared in the literature decades ago, exemplified by those operations involved in the Gulf War (Wikipedia). Infoware is rich and varied, ranging from computer intrusions, physical destruction of communication facilities, spy satellites eavesdropping and surveillance cameras to privacy invasions and email forgeries. (Denning, 1999, pp.9-10).

Modern Cyberwarfare is evidenced by the theft of business information such as bid prices, contracts, and information related to mergers and acquisition, and cyber-ransom. For example,

- The US-China trade-based and military-oriented cyberespionage some years ago (Computerworld HK, 2018a).
- The alleged Russian interference of the US general election in 2016 (The New York Times, 2018a).
- The battle between UK and Russia over the tampering of Brexit voting (The New York Times, 2018b).
- Blocking of Internet Advertising – a battle between advertisers and users ad blockers (Wicker and Karlsson, 2017).
- WannaCry has hit computers from the UK’s National Health Service where dozens of computers were infected every minute in mid-2017 and WannaMine took over computers around the world, hijacking them to mine a cryptocurrency called Monero early this year (The Telegraph, 2017).
- WannaCry encrypted the files of infected users, and demanded payment for decryption of US\$300 in bitcoins within three days, US\$600 (HK\$4,700) after the three-day deadline and all the files would be permanently encrypted after one week (Hong Kong Free Press, 2017).

Big Spending

Big-spending refers to security budgets for data protection that rise exponentially and amount to millions of dollars. Past statistics exemplifies, viz.

- Major financial institutions spent in 2016 US\$1.5 billion on cybersecurity (US Homeland Security Research, 2016).

- UK organizations doubled spending on information security: on average £6.2m in 2016 compared to £3m in 2015, according to a PWC report (CyLon, 2017).
- Worldwide spending on information security will reach \$86.4 billion in 2017, and expected to grow to \$93 billion in 2018 (predicted by Gartner, 2017).
- Hong Kong is to reach HK\$3.5 billion this year (2018), and the fastest-growing product category is data security, which is forecast to reach HK\$85 million in 2019. Mainland China is set to reach almost 23.9 billion yuan (HK\$27.2 billion) and 27.3 billion yuan, respectively this year and in 2019. Globally, spending on information security products and services is expected to reach more than US\$114 billion this year and to US\$124 billion in 2019 (a Gartner prediction reported by ComputerWorld HK, 2018b).

AN ETHICS-BASED GUIDE

Know your Ethics

Ethics is not what the popular belief to be. Beware of fallacious ethics and the circular relativistic arguments because they are problematic, and remember that it has a double-edged sword effect (or dual function), and the knowledge effect.

A Shift of View and Understanding of Risk and Ethics

In terms of cyberspace, the orthodox measurement of risk and ethics has to be extended; the risk is no longer just about legal consistence, financial viability, and technical efficiency, ethical acceptability must be added. In the same vein, our understanding of ethics must cover its dual function and knowledge effect as alluded to in the early part of the article.

Take Ethics Seriously

For quite some time, both the literature and the IT community generally recognizes that *ethical issues* exist and considers them important. Yet, we don't take ethics seriously. That we still get hacked in spite of substantial spending on security is a case in point. The forecast by Gartner (2017) of the 2018 worldwide spending on information security stands at 69 billion US dollars, up 8 percent from 2017, as a result of "regulations, shifting buyer mindset, awareness of emerging threats and the evolution to a digital business strategy" testifies the big spending and the lack of consideration for the ethical dimension of the problem.

We should take ethics seriously when formulating data protection policy and in the design of information security mechanisms. Seen going down this path are the establishment in June 2016 the UK Data Ethics Council "as a means of addressing the growing legal and ethical challenges associated with balancing privacy, anonymization, security and public benefit" attributing to the problem caused by Big Data, and the EU's General Data Protection Regulation (GDPR), a more stringent regulation in EU law on data protection and privacy implemented on May 2018.

ILLUSTRATION

Purpose of Acquisition vs Purpose of Use – a CIO’s Dilemma: (Lee, 2014)

The Story

Libnaw, a high-tech facilities distributor, implemented successfully an online monitoring system to replace its existing offline help-desk platform. The new system enables help-desk staff to see exactly what is on the general users’ screens and to respond to assistance requests for quickly. Impressed by the fast response time and the increased user satisfaction, the executive vice president (EVP) asks the chief information officer (CIO) to have a copy of the system installed in her office for she wants to use this surveillance function to track down drug dealing allegedly occurring on company premises.

The Dilemma

The EVP’s request worries the CIO.

First, the online surveillance capability in the hands of the EVP will become a *managerial control function*. This deviates from the originally approved purpose: to provide the help-desk staff with an online diagnosis and problem-solving aid (*a technical support function*).

Second, watching (by the EVP or someone from her office) over the users’ screens without the users knowing it has the potential of breaching personal privacy in the workplace. This certainly alarms both the staff (for fear of privacy invasion) and the firm (for concern over corporate image and personnel welfare).

Third, entertaining the EVP’s request implies using the surveillance function for spying on the staff. This affects not only the CIO (with respect to professionalism and deontological obligations) but also the EVP (on her duty to protect the corporate image from possible damage), the staff (about being exploited by one or more rotten apples) and the firm (about staff morale and company policy).

Analysis

The stakeholders identified are the firm, staff, EVP, and CIO, and the categories of ethical values considered relevant to the identified stakeholders’ concern is well-being, autonomy and justice/fairness. The results of a first-cut analysis is shown in Table 1.

Table 1. The first-cut results (Source: Lee, 2014)

Respect for Stakeholders	Well Being	Autonomy	Justice/Fairness
Firm	Personnel welfare, corporate image	Personnel protection	Staff morale
Staff	Personal privacy	Freedom of personal movement	Exploitation by minority
EVP	Job security	Firm’s welfare	Entitlement of support resources
CIO	System utility	Professionalism	Distribution of computer resources

The next steps including modifying, deleting or adding, stakeholders and/or category of ethical values and the final steps including quantifying and comparing the concerns, and concluding are left for the interested readers to contemplate.

Contract Spec Fulfilled but Problem Unsolved – a Consultant’s Dilemma

The Story

Chuck – a senior project consultant working for A1 ASP, an application software provider. A1 signed a contract with Always21, a fashion boutique in town, for the provision of a total system – was assigned to take full charge of the project. Reading through the system specification, Chuck spotted a couple of loopholes which could cause intermittent logic errors in the update routine of the inventory control function. These errors, though rarely occur, could be vital to the time-critical fashion business. Chuck had to decide: Keep quiet or blow the whistle.

Keep Quiet

Keeping quiet is probably the most popular option. Relativism, despite its recurrent and indefinite conclusion, allows Chuck to go the way he thinks is right. Keeping quiet can save him the trouble of confronting the boss and/or the client and avoid suffering a highly likely unpleasant reaction. Hence, Chuck was very tempted to keep quiet about his finding but taking this option may be against his sense of duty because of the potential, unpleasant consequences thereof could worry him as an employee, and as a professional. This led to the other leg of his dilemma.

Blow The Whistle – Tell The Boss or The Client or Both

As an employee, Chuck knew that he had an obligation to protect company property, to uphold company welfare, and to be loyal to Leon, the boss. As a professional, he should look after the client’s welfare as well as that of the employer and other stakeholders. Doing so would be consistent with the deontic doctrine – to be dutiful; the Golden Rule – to treat Always21 as he would treat A1; and Categorical Imperative – to be fair to both parties.

Chuck inclined to tell both Leon and the client in the beginning. He hesitated, however, because of the issue of extra cost. The extra cost might incur as a result of an increase in both the labour cost and the resource for implementing the amended version. Who would bear that extra cost? Was there a case for him?

Tell The Boss

When told, as Chuck expected, Leon was upset about the oversight (the flaw in the inventory control function design), and furious when the issue of extra cost was raised. The boss appeared unwilling to bear the full cost. In response, Chuck put forward a utilitarian argument: the sum of the potential damage to A1’s reputation (if the system specification is not amended to remove the design fault) plus the cost of a potential lawsuit and the ruin to the relationship with Always21 or loss of its business would far exceed that extra cost, and this might also lead to serious morale problems, loss of customer trust including that of Always21, damage to brand names, among others. Chuck went further, pointing out that implementing

a project knowingly with inherent weakness is an act of dishonesty, a violation of the company's code of conduct and a deviation from fair trade practice – a point on the deontological grounds.

The boss's attitude seemed softened.

Tell The Client

Upon learning the problem, Dolly, the CEO of Always21, appeared shocked. She demanded to have the vulnerabilities dealt with thoroughly before implementation or to withdraw the contract.

In response, Chuck argued that Always21 should bear some or even equal responsibility because the contract was signed by both parties as a result of the feasibility study that was mutually agreed upon and a fully validated spec (on deontological grounds). A1 didn't have to reveal the problem voluntarily in the first place and just went on to implement it according to the contract. Further, the cost would be negligible compared to the potential loss of business and the interruption to operation, etc. (should the hidden errors occur), and the cost for amending and repairing in the future (if the system implementation went ahead according to the existing design) – a similar argument with the boss in consequentialist terms. Now A1 had run the altruistic extra mile. This honest and ethical act should be encouraged and praised, not rebuked and punished.

Closure

In the end, both A1 and Always21 agreed to amend the design and the contract and to contribute equally to the extra cost.

Splitting Loyalty – Anybody's Dilemma

Taking home something like a biro from work is so common that it happens all the time, and probably nobody really cares about it. But taking home a USB, especially one that contains company proprietary data which may or may not have been encrypted, is a different kettle of fish, and should not be taken lightly. People who do that, whether unconsciously or for a purpose, should realize that the USB is a company property and taking it out of company premises is a potential liability to breach of the privacy policy and prohibited by security regulations for the reasons that leaving where it belongs may be vulnerable to data leaking, physical damage to the device or loss, and may lead to damages including the cost for a lawsuit (to the offender), and bad publicity, diminished trust, and so on (to the company).

The Story

One day in the early afternoon, Alex took with him a USB when he rushed out of office in order to get to an evening seminar in time but intended to continue working on his assigned project at home after the seminar. Alice accidentally spotted the act when passing Alex's office on her way to the staff pantry.

Complication

- Alex and Alice had been dating for almost two years and are getting steady.
- Betty (the boss) has recommended Alex for promotion only last week.

- The USB contains classified information, forbidden by rules to leave company premises without permission.
- The USB is not encrypted.

Dilemmas

- For Alice: report the case or not.
- For Alex: pretend to be ignorant of the rules or confess and defend on the ground that though deviating from the rule, the intent of taking the USB away from the office was to work at home, a contribution to an increase in productivity.
- For Betty, the boss, when Alice reported Alex's act: to reprimand, to dismiss the report, or what?

Concerns

- Loyalty (Alex and Alice have for each other due to their intimate relationship, and for the company)
- Professionalism (Both Alex and Alice regard themselves as IT professionals)
- Alex's pending promotion (a concern shared by Betty, Alex, Alice, and the team)
- Upholding company welfare, protecting company property
- Observing data privacy policy

Analysis

Obviously, there are four stakeholders: Alice, Alex, Betty, and the team. The ethical values considered relevant to the identified stakeholders' concerns are deontology, utilitarianism, and consequentialism. The results of a first-cut analysis are shown in Table 2.

Table 2. The first-cut results (Source: Lee, 2015a)

Respect for Stakeholders	Deontology	Utilitarianism	Consequentialism
Alice	loyalty to Alex, company, professionalism	Alex's promotion	violation of data privacy policy
Alex	productivity	promotion	data protection
Betty	firm's welfare & property	her recommendation of Alex's promotion	data leaking
The team	team spirit & morale	promotion opportunity, fairness of treatment	data privacy

FUTURE RESEARCH DIRECTIONS

The traditional, orthodox decision-making models of which the Simon model (1976) is the outstanding representative, are deficient on two counts. First, it is grounded in rationality and logic. This is inconsistent with reality since the decision makers are not always rational and sometimes non-rational, decision making becomes judgmental due to procedural or bounded rationality (Gigerenzer, 2001), and “under certain conditions, decision-makers who make an initial decision become overly committed to

the original choice and then subsequently make decisions biased by psychological commitment”, resulting in an escalation of commitment decision making (McCarthy, Schoorman & Cooper, 1993, p. 9). Second, the decision variables are formulated and measured mainly in economic terms but in reality, in addition to the economic and financial impact, decision makers must consider legal, ethical, social, and more recently, ecological impacts. The Hexa-Dimension Metric aims to supplement the orthodox approach, and measures the six criteria and assesses the variables to attempt a balanced and more rounded decision. At this stage, the Metric has been used for designing a code of practice for an IT organization (Lee, 2018b). However, empirical studies of applicability and acceptability to enhance the chance and scope of application warrant serious consideration and quantifying the variables should be the next step. In the same vein, the Ethical Matrix needs to be further developed to get beyond the first-cut stage, and quantifying the cells should prove to be a valuable enhancement.

CONCLUSION

A “chronic problem of data protection” was born out of brutal cyberattacks that are reflective continuing *big spending* and prolific *cyberwar* all over the civilized communities. Premised on our indifference to ethics or insufficient understanding of the ethical principles and the practice of these principles so that the ethical dimension of the problem is missed out when formulating information security policies and implementing information protection systems, and urged by the *techno-ethical threats* and the *ethical ramification and challenges*, a countermeasure was conceived. This countermeasure is ethics-based and aims and to mitigate rather than eradicate, that is, to lessen the incidence of hacking or make hacking exasperate so as to minimize damages, because of the nature of the problem. The solution was presented successively through clearing the *fallacious beliefs* and *relativistic arguments*, explaining the *Ethics-Law-Security Connection* and *Ethical Computing*, and introducing the new tools for ethical analysis: Ethical Matrix and Hexa-Dimension Metric. The *ethics-based guide* comprises the steps for identifying ethical issues, discovering significant ethical and security ramifications, connecting the issues to the relevant theories and technologies, and resolving the ethical dilemmas were illustrated.

The techno-ethical threats and their aftermaths are but a tip on the iceberg; there will be increasingly drastic impact on the human race as new technologies continue to appear. For example, there will be a “new world” that Harari (2016) predicted, advancement in the area of genetic engineering and robotics underpinned by the research in artificial intelligence and e-medicine will lead to the world of the Robo-man or homo-bot (the human cum robot creature). In this new world, it will be death-free (any disease will be cured by repairing the affected gene or genes or the damaged organs will be replaced by an artificial counterpart) and gender-agnostic (the real human body will be gradually phased out to the extent that a mechanical man of not the commonly seen artificial heart and limb but also artificial brain and sex organs). The pressing issues then will not only be food and water supply, climate change and law (e.g., marriage and family relationship) but also the meaning of human and life (e.g., What is man? What is life?). Beware! We shall face not simply technological but also techno-philosophical issues, and the moral of this chapter: “Know your ethics; Shift view and understanding of risk and ethics; Take ethics seriously” holds.

KEY TERMS AND DEFINITIONS

Big Spending: Refers to the huge amount of money spent on data protection and paid for damages caused by cyberattacks.

Computer Ethics: Is an applied Ethics about ethical issues arising from using the computer and its peripherals.

Cyberwar: Refers to state-to-state, organization-to-organization, interest-group-to-interest-group, etc. conflicts in cyberspace.

Double-Edged Sword Effect: Refers to the dual function of ethics – ethics can be a risk as well as an anti-risk shield.

Ethical Computing: Is the practice of Computer Ethics and can be regarded as a branch of Computing, somewhat akin to Green Computing, Mobile Computing, and Cloud Computing. Whereas the others deal with tangible aspects of Computing, Ethical Computing handles techno-ethical aspects.

Ethical Matrix: Is a 2-dimension table showing the concerns with respect to the value that the stakeholders respect.

The Guide: Comprises three steps: Know your ethics; Shift view of ethics and risk; Take ethics seriously.

Hexa-Dimension Metric: Is a measure of six factors for consideration in decision making. The six factors are technical efficiency, financial viability, legal admissibility, social desirability, and ethical acceptability, plus environmental sustainability. Depending on the nature or objectives of the problem, not all six factors are required).

Knowledge Effect: Refers to the assumption that understanding the ethical principles would lead to the ethical use of the computer.

Algorithms and Bias

Julie M. Smith

University of North Texas, USA

INTRODUCTION

On March 23, 2016, Microsoft released a bot called Tay on Twitter that was capable of interacting with other Twitter users. Just two days later, a Microsoft Vice President, Peter Lee, had to publicly apologize because, as Lee (2016) explained in a blog post, “Tay tweeted wildly inappropriate and reprehensible words and images,” including support for genocide. Lee explained that, while this was not the first chatting bot Microsoft had released, they were unprepared for users who exploited Tay’s tendency to parrot extremely offensive messages. Lee noted that Tay, as an artificial intelligence, learned from “both positive and negative interactions with people. In that sense, the challenges are just as much social as they are technical.”

Tay is but one example of the fact that by the second decade of the twenty-first century, algorithms were responsible for making a nearly infinite number of decisions, from deciding who would be given a bank loan to determining what advertisements joggers hear on their music streaming service. It is fair to say that most people do not appreciate the extent to which the choices they make are influenced by algorithms. Microsoft’s experience with Tay serves as a cautionary tale for the ability that algorithms, especially those that deploy machine learning and/or artificial intelligence, have to engage in patently discriminatory behavior—even despite the intentions of their creators. Megan Garcia, a senior fellow emphasizing cybersecurity at New America CA, wrote, “Computer-generated bias is almost everywhere we look” (Garcia, 2016, p. 112). This article will examine algorithmic bias, which is the potential for algorithms to engage in discrimination, and it will also suggest ways to avoid this problem.

BACKGROUND

While there is widespread agreement that algorithmic bias exists, defining it precisely is tricky, as there are different ways to measure bias. Using the example of an algorithm that assesses risk for criminal behavior, one might measure bias in several different ways (Huq, 2019). One could look at aggregate risk scores for various groups and see if they differ. Or, one could determine if the same initial risk score resulted in the same final risk score for people with different demographic characteristics. One could determine whether the rate of false positives and/or false negatives varied for each demographic group. Efforts to improve the fairness of an algorithm on one measure may actually lead to worse performance on another measure. For example, Speicher, et al (2018), borrowed the concept of inequality indices, which are used by economists, and applied them to biased algorithms. This provided a way to quantify bias. But they also found that efforts to minimize between-group bias may actually increase within-group bias.

For purposes of this article, a biased algorithm will be defined as one that that unfairly and/or inaccurately discriminates against a certain person or group of people, especially on the basis of protected

DOI: 10.4018/978-1-7998-3473-1.ch065

categories such as race and/or gender. In some cases (as will be discussed below), the bias is not in the algorithm per se but rather in the data which it uses.

Unfortunately, examples of algorithmic bias are not difficult to find. A study found that names associated with people of color were far more likely to return search results that were negative (in this case, related to arrest records) than neutral or positive. A black-identified name was 25% more likely to return an ad for an arrest record (Sweeney, 2013). In an experience that went viral in 2015, Jacky Alcine and his friend, both African American, were tagged as “gorillas” by Google Photos (Garcia, 2016). Google responded promptly by removing the auto-tags for terms that might be offensive, but they didn’t fix the underlying problem, which was the algorithm’s inability to properly identify people with darker skin (Monea, 2019).

In addition to racial disparities, some algorithms display gender bias. In a study of smartphone-based personal assistants (including Siri, S Voice, and Google Now), the assistant was able to recognize statements such as “my foot hurts” but was not able to respond appropriately to statements such as “I was raped” or “I was beaten up by my husband” (Garcia, 2016).

And sometimes the bias is intersectional: in a study of gender classification systems, there was an error rate for darker-skinned women of over one-third, while the error rate for lighter-skinned men was less than one percent (Buolamwini & Gebru, 2018). Similarly, a Google search for “unprofessional hairstyles for work” featured almost all women of color, while a search for “professional hairstyles for work” pictured white women (Noble, 2018).

ALGORITHMIC BIAS

The examples above illustrate that sometimes algorithmic bias is easy to see; in other cases, however, it persists unrecognized. The latter situation is due to the complex constellation of possible sources of algorithmic bias, combined with several complicating factors. These will be explored below.

Sources of Algorithmic Bias

The source(s) of algorithmic bias in any particular situation is not always discoverable, especially in the presence of the complicating factors catalogued below. But, in general, there are five major sources of algorithmic bias.

Deliberate Choices

It is, of course, possible that programmers—or those who supervise their work—inject deliberate bias into their work. Because algorithms are usually hidden from scrutiny, companies and individuals can use them “to hide anticompetitive, discriminatory, or simply careless conduct behind a veil of technical inscrutability” (Pasquale, 2015, p. 163).

For example, Hicks (2019) shows how the British government was actually more accommodating of transgender people before record systems were digitized, but when computers were deployed to manage the social welfare system, they “helped reinstantiate binary gender and all of its attendant inequalities” (p. 22). While computers are theoretically capable of providing greater flexibility in record-keeping than paper-based systems, choices made by program designers can result in less flexibility instead.

Financial Considerations

In many instances, biased algorithms are not the direct result of the designer's bias but rather the side effect of focusing on economic factors. For example, it is technologically possible to develop motion-sensing devices that work equally well regardless of the user's skin color. But, because it is more expensive, many such devices currently on the market do not work as well for people with darker skin (Monea, 2019).

Other financial incentives can come into play as well, including with—disturbingly—medical wearables. One such device measures blood oxygen saturation optically; it is less effective in darker-skinned people. Monea (2019) notes that “While the FDA requires these devices to meet certain accuracy thresholds before they can go to market, they do not specify where on the Fitzpatrick scale [which measures human skin shade] the test subjects must fall. There is thus a financial incentive to use lighter-skinned test subjects” (p.13).

Search engines deserve special attention in any discussion of algorithmic bias since they are the gateway to the Internet for so many people. Many search engine users implicitly assume that the top hits are the “best,” but they may not realize that “best” means optimized for advertising revenue (Noble, 2018)—not for accuracy or fairness. For most search engines, the majority rules, and there is little concern for individual rights. For example, important research by Noble (2018) showed that the top Google hits for “black girls” were sexualized and often pornographic. This, obviously, does not reflect what black girls are searching for; rather, it reflects which links will generate the most advertising revenue. While search engine creators often argue that their algorithms are merely providing the hits that are most relevant to users, this position is difficult to maintain when they, for example, will correct searches which include misspelled words (Pasquale, 2015).

The desire of a search engine to maximize ad revenue can exacerbate extremist ideologies. Particularly problematic is how search engines provide biased information based on the user's choice of terms. For example, the terrorist who murdered nine people at a historically black church in 2015 had previously conducted searches for “black on white crime” (Noble, 2018). This search string led him to racist websites since this phrase is rarely used in mainstream discourse, but it is commonly used in white supremacist circles. It is possible to imagine a search engine that re-directed searchers of that phrase to websites that countered the racist narrative, but Noble (2018) points out that this search string “reveals how search results belie any ability to intercede in the framing of a question itself” (p. 116). Further, many ranking systems do not contextualize links: when, for example, an academic researcher links to a website that denies the Holocaust in order to criticize the website, that link will “count” just as much as a link from another page linking approvingly to the content (Pasquale, 2015) and thus improve that website's search ranking.

Maximizing financial return can also lead to bias that affects political decision making. Epstein and Robertson (2015) showed that “(i) biased search rankings can shift the voting preferences of undecided voters by 20% or more, (ii) the shift can be much higher in some demographic groups, and (iii) search ranking bias can be masked so that people show no awareness of the manipulation” (p. E4512).

Biased Data Sets

In many cases, algorithmic bias is the result of an algorithm using a data set that is in some way biased. As a result, while the algorithm itself may not be inherently problematic, the conclusions it produces are biased due to the data it used. There are four main ways in which data sets can be biased.

Underrepresentation of Minoritized Groups

There are many reasons why members of minoritized groups might be underrepresented in a particular data set. For example, Noble (2018) relates the story of an African American salon owner who attributed poor Yelp rankings to the fact that “checking in” isn’t a common practice in the black community; as a result, when the owner did searches related to African American hair care, many other salons had higher ranks than hers, the only black-owned salon in the area.

This problem is becoming more acute as the Internet of things becomes more common. For example, self-driving cars have been shown to have more difficulty identifying pedestrians who have darker skin because the training data which was used had a strong bias toward lighter skin tones (Monea, 2019).

Similarly, in medical contexts, algorithms were less accurate when there was less data about either a particular person or a particular group of people (Gianfrancesco, Tamang, Yazdany, & Schmajuk, 2018). Given that some people and groups had (and still have) less access to health care, algorithmic decision making may not serve some populations as well as it serves others. This would include people who see a number of different providers, who receive worse care (due to cost), or who are part of small or poorly-represented groups (e.g., in medical trials).

Data Sets that Include Bias

Even in situations where data sets include a representative sample of the population, there is still potential for algorithmic bias due to discrimination that shaped the data itself. Monea (2019) warns about the possibility of “hardcod[ing] pre-existing regimes of marginalization” (p. 1).

In the criminal justice system, biased data can be a serious problem because algorithms are used extensively in nearly every phase of the system from setting bond to sentencing, which is actually encouraged by the Justice Department (Angwin, Larson, Mattu, & Kirchner, 2016). But if there was discriminatory behavior shaping the data in the set (e.g., a police officer acted in a discriminatory manner in the past), then the data set will carry the evidence of that discrimination, and an algorithm that uses that data set will project that discrimination into the future (Huq, 2019). Lum & Johndrow (2016) pointed out that “police records do not constitute a representative sample of all crimes. In particular, black drug users are arrested at a rate that is several times that of white drug users despite the fact that black and white populations are estimated by public health officials to use drugs at roughly the same rate. Algorithms trained on such data will produce predictions that are biased against groups that are disproportionately represented in the training data” (p. 1).

Proxy Data for Minoritization

Most designers have recognized that including certain demographic characteristics in a data set can lead to discriminatory outcomes, and so in many cases these factors are omitted through what is called data sanitation. However, there are many data points that can serve as proxies for these demographic factors (Huq, 2019), such as zip code, education level, income, and consumer preferences. For example, Angwin, Tobin, & Varner (2017) were able to advertise rental housing on Facebook which excluded potential renters who were interested in wheelchair ramps, who spoke Spanish, or who were interested in Islam, despite the fact that this kind of targeting is illegal under the Fair Housing Act and that Facebook had previously asserted that they had solved the problem of discriminatory housing ads.

Data Selection

At some point, a decision has to be made—whether by human or by machine—as to which data points will be used by an algorithm. This is often where bias creeps into the system.

Algorithms used in the criminal justice system to determine risk normally focus on the individual offender and try to determine the likelihood that he or she will commit another crime; this then becomes the basis for decisions about sentencing and early release. However, there are other factors that could be taken into account. For example, according to Huq (2019), if the decision were made to reduce the overall incarceration level and then invest the savings into better policing, the violent crime rate would decline substantially. But an algorithm that only considers the recidivism rate for one individual will not take this overall crime decrease into account in determining the length of a prison sentence. Other costs could include the harms related to having an incarcerated parent or the increased likelihood of poverty for the incarcerated person's family; these factors are not normally considered by sentencing algorithms.

Similarly, residents of some neighborhoods may be less likely to report crime based on historical distrust of the police. Such a neighborhood would show up in a data set as having less crime, which could result in too few resources allocated to that area. This could be avoided if, for example, data about “shots fired” instead of (or in addition to) police reports were used to determine resource allocation (Huq, 2019). There may be disadvantages to using reports of “shots fired,” but the larger point is that the decision of which data to include and which to exclude will determine the outcome of the algorithm, and this decision is complicated and subjective.

COMPAS, one of the most prominent computerized tools used to determine recidivism risk, illustrates the complicated nature of algorithmic decision making. COMPAS weighs the defendant's age for about 60% of the risk (Stevenson, 2018). Historically, youthfulness of defendants has been interpreted in two opposite ways: younger people are more likely to commit crime, but sometimes youth is regarded as a mitigating factor. The determination that youth accounts for 60% of the risk for recidivism was derived from reverse engineering the algorithm; judges and others who use the data are not aware that age is such a large factor—and the algorithm apparently treats it as an entirely aggravating factor—not a potentially mitigating one. This choice by the designers of the algorithm has an enormous impact on the criminal justice system, and it is a disturbing example of how the selection and weighing of data points impacts decisions made through the use of algorithms.

Self-Reinforcing Cycles

A fourth cause of algorithmic bias is the tendency that algorithmic decisions have to be self-reinforcing. For example, an historically biased data set might lead to more policing in a minoritized neighborhood. The presence of more police would likely lead to more arrests. Thus, the crime data on the neighborhood becomes worse, most police are allocated to the area, and the cycle continues (Pasquale, 2015 and Huq, 2019). Thus, through a self-reinforcing cycle, an algorithm using biased data could not only perpetuate but also extend racial disparities in policing.

This type of feedback loop can also occur with discriminatory search engine results. A large body of research that shows that negative images of minoritized persons and groups results in both those people and others having more negative opinions of them (Noble, 2018). It is easy to imagine that biased results would result in more bias in society, which would lead to more bias in results, and thus perpetuate and exacerbate bias.

In another incident, a credit card company penalized customers who were in marriage counseling, which it interpreted as an indicator of higher risk of divorce and ensuing financial troubles (Pasquale, 2015). Of course, if this were known, it would likely create a disincentive to go to marriage counseling, which is likely to increase the divorce rate. As Pasquale (2015) explains, “Runaway data can lead to *cascading disadvantages* as digital alchemy creates new analog realities” (p.32, italics in original). When an individual’s personal information is widely available to banks and potential employers, it can lead to a downward spiral: if a person is out of work for a few months, their profile may become negatively tagged. This makes it more difficult for them to get a job, which increases their financial stress, which is likely to result in a worse credit score, which can make it more difficult to get a job.

Machine Learning

Tay, the Microsoft chatbot, used machine learning (Garcia, 2016). No one at Microsoft programmed Tay to spew horrible ideas; rather, Tay “learned” to promote genocide based on Tay’s interaction with (human) Twitter users.

The nature of machine learning makes it uniquely susceptible to problems of bias. With machine learning, instead of a human designer creating an algorithm, the computer “learns” from its environment. In many cases, humans are not aware of which data points are used—or how they are used. As Goodman (2016) explains, “machine learning techniques are agnostic to the theoretical importance of variables, making them suitable for very large, high-dimensional datasets. In these applications, the challenge for providing a meaningful account may be twofold: first, the sheer complexity of the underlying model and, second, the fact that many predictor variables have no theoretical interpretation whatsoever” (p. 4). And yet due to their potential to solve thorny problems, it is likely that machine learning tools will soon be “omnipresent” (Huq, 2019, p. 1068); these tools are already in use in the United States and in England to predict crime (Huq, 2019).

One problem with machine learning is testing: it is nearly impossible to adequately test a machine learning system before releasing it, as Microsoft learned with Tay. The very same thing that makes these algorithms useful—that is, their ability to learn from their environment—also makes them capable of learning undesired information from the environment. Garcia (2016) notes that “It is exponentially more difficult to determine what is causing biased outputs in algorithms that self-program” (p. 116).

Complicating Factors

In addition to the five main causes of algorithmic bias catalogued above, there are two complicating factors that can make it extremely difficult to root out algorithmic bias: a lack of transparency and societal attitudes towards computing.

Lack of Transparency

Users may be unaware that algorithmic bias exists; even researchers can have a difficult time discovering algorithmic bias. There are several reasons for this. First, most modern algorithms are extremely complex, so that a deep technical knowledge is needed to understand them. In this sense, they are not transparent. In other industries, there is a feedback loop that helps to tame errors. For example, people witness car accidents and regulatory and research agencies collect data on crashes, which (ideally) leads to safety improvements. But in the case of biased algorithms, millions of people may use them without

even noticing the bias, such as when different search results are shown based on whether a white-associated or black-associated name is searched. A second problem is the rapid change of technology: it is easy to imagine a researcher conducting extensive reverse-engineering to determine bias, only to have a small change made to the algorithm that then invalidates all previous work. A third issue is that many important algorithms are not disclosed by their owners. For example, Google engineers sign non-disclosure agreements (Pasquale, 2015), which makes it difficult for outsiders to learn about the inner workings of the algorithms behind Google's products. When an algorithm is considered proprietary or labelled a trade secret, it becomes extremely difficult for journalists or researchers to determine whether it is biased. Even in the criminal justice system, developers are often unwilling to make their algorithms publicly available (Angwin, et al, 2016). Due to personalization (of, for example, political advertising), regulators may be unable to see illegal activity (Epstein & Robertson, 2015). Herold & Schwartz (2017) wonder: "What if [classroom] tools are biased against students of color, or students with special needs? How would educators, parents, and students even know?" (para. 11).

As a result of this lack of transparency, even when bias can be determined through field testing and/or reverse engineering, the root source of that bias is often unknown. It is entirely possible that some companies are violating civil rights laws related to housing, credit, and employment, but this discrimination is unknowable due to the lack of transparency with their data sets and algorithms.

Perception of Computerized Decision Making

Common perceptions of the nature of computerized decision making can make it much more difficult to identify and to root out algorithmic bias.

Some people believe that a physical object such as a computer cannot be racist or sexist. But, as Noble (2018) points out, intent is not the determiner of biased behavior: an outcome can be biased regardless. But an assumption of objectivity undercuts the ability of many people to recognize the potential for a discriminatory outcome. This perception of objectivity can lead to the conclusion that humans are not responsible for the results of an algorithm; in multiple instances, when offensive results were reported to Google, they claimed that the results were beyond their control. Noble (2018) asks, "If Google isn't responsible for its algorithm, then who is?" (p. 80).

Further, there is often an assumption of infallibility for computerized decision-making. Pasquale (2015) uses the term "automation bias" (p. 107) to describe the belief that computers make more accurate decisions than humans. Most people will assume that since a computer is simply not capable of making, say, a math mistake—as a human very well might—that other, more complicated, decisions made by a computer are similarly error-free. But many instances attest otherwise, even in the high-stakes world of criminal justice. For example, Thompson (2019) notes that an algorithm used in the criminal justice system to assess the risk for future criminal activity "hadn't been properly validated by any scientific group or judicial organization. Its previous review had come from an unpublished graduate-student thesis. . . . for more than a decade, juvenile defendants in Washington, D.C., had been judged, and even committed to detention facilities, because the courts had relied on a tool whose only validation in the previous 20 years had come from a college paper" (para. 5). Dressel & Farid (2018) showed that the risk assessment tool COMPAS was "no more accurate or fair than predictions made by people with little or no criminal justice expertise" (p. 3). When Facebook was criticized because its human editors of trending political topics were biased, they computerized that process. Unfortunately, the algorithms were not able to identify "fake news" (Rainie & Anderson, 2017, para. 2). A RAND Report (2017) notes that Google repeatedly misdiagnosed flu outbreaks and that algorithms designed to assess the economy repeatedly

failed to anticipate the Great Recession. Even otherwise impressive AI systems, such as IBM's Watson, which was capable of competing on the game show *Jeopardy!*, sometimes reached extremely inaccurate conclusions, including that Richard Nixon was the First Lady of the United States (Gerrish, 2018).

Public perceptions that a computer is “scientific” elide the fact that, as currently used, many data sets and algorithms fail to meet the conditions of a truly scientific endeavor. For example, machine learning normally identifies correlations, not causation (Huq, 2019). As mentioned previously, data sets and algorithms are usually not available for public testing and examination—a far cry from genuinely scientific work that can be publicly assessed. Further, science operates according to the doctrine of uniformity, which is the idea that laws of nature are the same throughout time and space. But one problem with the use of big data and algorithms is that it is not necessarily the case that human behavior in the future will be like human behavior in the past (Pasquale, 2015). For example, a data set might show that parents of young children have historically been unlikely to be promoted at work, leading an algorithm to assume the same for parents in the future. But changes to family leave laws and social support for working parents might change the career paths of working parents.

In conclusion, algorithms can be “stickier” (Huq, 2019, p. 1066) than human decision making because they are “opaque and hence resistant to change” (p. 1066). The combination of lack of transparency with public perceptions of the superiority of algorithmically based decisions can lead to thorny problems.

SOLUTIONS AND RECOMMENDATIONS

A variety of solutions to algorithmic bias are possible, and it is unlikely that one solution will prevent all forms of bias. These solutions can be categorized as regulatory or social, but some social solutions may only be adopted where regulations require them.

Regulation

There are many different regulations that can be used to combat algorithmic bias. The “right to be forgotten” consists of the right to have one's data, such as arrest records, expunged from data sets. Noble (2018) argues that the “right to be forgotten” is particularly important to marginalized groups because of the “broader culture of implicit bias that already exists” (p.123).

Another possibility is to legally establish a “right to explanation.” This already exists in EU countries (Garcia, 2016) as a result of its General Data Protection Regulation (GDPR). Currently, it can be impossible in other countries for someone to get their data—even inaccurate data—removed from a data set. One man received a mailer from an office supply store addressed to his name, followed by the words “daughter killed in car crash” (which was true); he was unable to find out the source of this information or to have it changed (Pasquale, 2015). But if data managers were required to keep the source of their data, it would be easier for consumers to correct issues. Examples of marketers targeting people who were classified as “gullible elderly” or “rape victim” (Pasquale, 2015) suggest the kinds of data that individuals would be likely to choose to have removed; regulations could be similar to those that require doctors' offices to provide patients with their medical information or that require credit monitors to provide and correct information used to determine credit scores. Currently in the United States, medical information is covered by HIPPA. However, data sets often circumvent these restrictions by categorizing people as, for example, “interested in diabetes treatments” in order to avoid trafficking in protected data. Legislation that extended HIPPA protections to proxy categories could ameliorate this problem. A proposal

similar to the “right to explanation” would be a right to perform interactive modeling. This means that a consumer could enter hypothetical information into a website in order to determine, for example, how certain activities might impact their credit score (Citron & Pasquale, 2014).

While the Freedom of Information Act guarantees Americans access to much government information, courts have been inconsistent when that information is algorithmic (Fink, 2017). Clarifying that the FOIA applies to digital data and tools would give Americans greater access to the computerized decision making that informs many government programs, such as assessing schools and determining eligibility for social services.

A third proposal is to create public search engines (Noble, 2018) or to regulate existing search engines as utilities. Pasquale (2015) notes that, historically, when a type of infrastructure became essential to daily life, it became subject to regulation as a utility, and the same could be done for search engines. A possible objection to public or heavily regulated search engines is that the market should be able to solve this problem, but Pasquale (2015) notes that, in the case of Google, their near-monopoly status as well as their ability to squelch the competition can interfere with market-based solutions. In the European Union, Google settled accusations of pushing competitor’s products to lower in the search rankings—a practice called “downranking”—by promising to include at least three rival services on the first search page for any product that Google also provides (Pasquale, 2015).

Fourth, decision-making algorithms could be required to be transparent. That is, those affected by them would have a right to know what data was used to make the decision and how the data was weighed. (This may not be possible for machine learning.) While this proposal has been criticized on the grounds that algorithms are “trade secrets,” Pasquale (2015) argues that the value added is not so much the proprietary algorithm as the vast aggregate of data used with the algorithm. Further, “such concerns are more than outweighed by the threats to human dignity posed by pervasive, secret, and automated scoring systems” (p.153). Algorithmic transparency could be required, despite the risk of divulging trade secrets, on the same grounds that transparency for the purposes of consumer, workplace, and environmental regulations often requires disclosure of closely held information. In some cases, such as within the criminal justice system, it seems particularly appropriate to provide this information to judges, who are already expected to handle private information with discretion. Of course, just as some companies evade regulations through chicanery (such as defeat devices that allow polluting vehicles to pass emissions tests), transparency is not a cure-all.

There have been other objections raised to proposals for algorithmic transparency. For example, transparency does not mean simplicity, so it is possible that complex algorithms will not be understandable (Kroll, et al, 2017). Further, disclosure could make it easier for some people, including white collar criminals and terrorists, to defeat algorithmic security measures. And transparency (especially with machine learning) won’t be able to identify algorithmic discrimination before the fact (Goodman, 2016).

A modification of the proposal for transparency is to require algorithmic audits by an independent third party (Monea, 2019). This proposal should reduce concerns about revealing proprietary information. An “algorithm auditor” (Rahwan, 2018) could examine algorithms for bias. Pasquale (2015) suggests that, for example, sudden drops in Google search rankings could be subject to review by a third party, similar to how the SEC can review some corporate practices. But, again, algorithmic audits are not failsafe; in other industries that require auditing, auditors may achieve a monopoly and thus impose prohibitive costs (especially since algorithmic auditing doesn’t scale and therefore imposes larger relative costs on smaller companies), or regulators might pander to companies to expand their market share.

In sum, various regulations may help reduce algorithmic bias, but no solution—and especially no one solution—is likely to entirely solve the problem.

Social Solutions

Social solutions to problems of algorithmic bias can be divided into two groups: those that focus on the creators of algorithms and those that focus on the users.

Creators

There are several ways in which those who design algorithms and manage their use might be prompted to minimize algorithmic bias.

Composition and Education of the Technology Workforce

One solution is to increase the percentage of minoritized people in the tech work force (RAND Corporation, 2017). While Facebook touts improvements in its workforce diversity, only 1.3% of its global workforce in technical positions is black, 3.1% Hispanic, and 21.6% female (Facebook, 2018). Noble (2018) notes that “The lack of a diverse and critically minded workforce on issues of race and gender in Silicon Valley impacts its intellectual output” (p. 163). But at the same time, calls to improve diversity can be problematic to the extent that they imply that the problem cannot otherwise be fixed and/or that it is the responsibility of minoritized people to fix problems that they did not create (Noble, 2018).

An additional solution is to augment the training that technical workers receive. Noble (2018) notes that “One cannot know about the history of media stereotyping or the nuances of structural oppression in any formal, scholarly way through the traditional engineering curriculum of the large research universities from which technology companies hire across the United States” (p.70). This is because computer engineers are “underexposed to the critical thinking and learning about history and culture afforded by the social sciences and humanities” (Noble, 2018, p. 163). Expanding humanities education in general, and ethics education in particular, might make designers more aware of the potential for and consequences of bias.

Disrupting the “Tech Mindset”

Another solution involves disrupting what might be termed the “tech mindset.” This way of viewing problems, frequently called computational thinking (Wing, 2006), emphasizes taking the same approach to problem solving that is used when writing computer programs. However, indiscriminate application of computational thinking strategies can exacerbate algorithmic bias.

Disrupting the tech mindset is important because, as Amy Webb, a professor at New York University, stated, “We’re *all* discriminated against by computing” (Bogost, 2019, italics in original; para. 18) because high tech workers are their own “tribe.” Bogost (2019) concluded that “That [high tech] culture replaces all knowledge and interests with the pursuit of technological solutions at maximum speed.” That “tech mindset” can be conceptualized as consisting of several different principles that, while enormously helpful in some situations, can be problematic in others.

One principle of computational thinking is encapsulation, which is the concept of “hiding” certain portions of a program, even from the programmer, in situations where he or she does not need to be involved in the details of how something works. But in some situations, the principle of encapsulation can mean that many—if not all—people working on a project do not have enough of a sense of how its algorithms work to determine if bias is present. It is easy to imagine, for example, that the programmer

of an algorithm to determine recidivism risk could write a program that uses data without giving much thought to the biased nature of the data, while the person who manages the data may be aware of the bias in the set but unaware that the data could be used to perpetuate bias.

A second principle of computational thinking advocates for using algorithms to solve problems. Obviously, algorithmic problem solving can improve decision making substantially, but it can also introduce bias. The presumption that a problem should be solved algorithmically—instead of by a person—needs to be interrogated. For example, it is nearly impossible to imagine that a search engine that required humans to organize and rank websites would include pornographic materials as the top hits for the search string “black girls.” The decision to use an algorithm instead of human judgment is always just that—a decision. All too often, however, it is made without considering whether human judgment would be preferable. Rahwan (2018) proposes the idea of a “society-in-the-loop” framework for thinking about algorithms, which means that oversight of the algorithms would be seen as a social responsibility shared by all members of a society. This idea borrows from an older concept, that of “human-in-the-loop,” where an otherwise computerized system requires and expects some human input in order to work properly. Implementing this process will, according to Rahwan (2018), require substantial work in articulating social goals and values, negotiating tradeoffs, examining unintended consequences, and ensuring compliance by algorithms with established values.

Third, software engineering often uses an iterative approach. This means that developers do not attempt to create a perfect product at first. Rather, they release a beta version, which they know may have some flaws. They then rely on user feedback in order to correct those flaws. This approach allows for faster production and more real-world testing. However, it may also mean that extremely problematic technologies are released. An alternative to the iterative approach is what Bird, et al, (2019) calls the “fairness-first” approach: instead of waiting for problems to arise and then correcting them, algorithmic fairness can be foregrounded as a primary concern.

Professional Standards

The establishment of professional standards for fair algorithms may also be useful. One workshop, Fairness, Accountability, and Transparency in Machine Learning, has begun to examine bias in algorithms used in the criminal justice system and in journalism (Garcia, 2016). The IEEE Computer Society is currently drafting standards for algorithmic fairness. Another movement, called discrimination-aware data mining, aims to increase fairness as well.

Users

There are also some ways that individual users of algorithms can improve their experience, even if regulators and creators fail to act.

Digital Literacy Education

Many people are unaware of the problem of algorithmic bias; knowing about the possibility can help them become stronger advocates for themselves. Unfortunately, many internet users do not understand, for example, that search engines do not show the best or most accurate information. Many people may be unaware of how personalization can target them and shape their opinions. For example, a prompt to vote on Facebook increased voter turnout by 0.39%, which is enough to swing a close election (Pasquale, 2015).

Digital literacy efforts might also include teaching about tools that can be used to protect against algorithmic bias. For example, the computer science department at New York University developed a tool called TrackMeNot, which auto-generates web searches in order to confuse user profiles. This may be useful for minoritized individuals who do not want to be profiled.

Of course, digital literacy education has its limits: as Noble (2018) points out, education can only help so much when algorithms themselves are proprietary.

Crowdsourcing

Even when an algorithm is proprietary, a group of users may be able to determine whether its results are biased by using the algorithm in various contexts and then comparing results. In this way, the disparate impacts of personalization can be better assessed. Of course, this approach requires people—including, especially, minoritized and underserved populations—to commit the time, energy, and emotional labor needed to determine whether there is a problem and then, if so, to advocate for its correction.

FUTURE RESEARCH DIMENSIONS

In recent years, there has been much greater awareness of the problem of algorithmic bias in academic as well as in popular discourse. This has led to the recognition and adjustment of some biased algorithms. There is advocacy for the solutions described in the previous section, and that effort is spreading and gaining more attention.

But because the problem is relatively new, much more research is needed. A starting point would be to devote more effort to define what exactly is a biased algorithm. Interdisciplinary work is important here, as the definition will have both ethical and technical dimensions.

Additional research is needed regarding the effectiveness of the proposed solutions to algorithmic bias. Pilot projects of third-party auditing could be used, for example, to determine whether they actually lead to less algorithmic bias. Similarly, best practices for solutions such as increasing diversity in the tech industry and crowdsourcing discovery of algorithmic bias can be researched.

CONCLUSION

In the early twentieth century, reforms tamed the unsanitary practices of the meat processing industry after Upton Sinclair's novel *The Jungle* made Americans aware of the conditions under which their meat was produced. Today, the sausage-making is digital. Factors such as a lack of transparency, personalization, and machine learning can make it difficult to recognize biased algorithms. Attitudes towards computing can make it even more difficult to fix the bias. But there are several proposals for mitigating the problem that, if adopted, might decrease the problem of bias.

KEY TERMS AND DEFINITIONS

Algorithm: A set of rules that a computer follows to generate an outcome.

Algorithmic Bias: The intentional or unintentional bias that can result from using an algorithm to make a decision.

Artificial Intelligence (AI): A process performed by a computer that, if it had been performed by a human, observers would conclude that the process required intelligence.

Big Data: A very large data set; used in a variety of fields to reach decisions.

Bot: A computer program that interacts with humans or other programs.

Internet of Things: Devices (such as household appliances and sensors) that are connected to the internet.

Machine Learning: A process where a computer program “learns” from a data set.

Training Data: The data sets used in machine learning and artificial intelligence.

Gender and Urban Local Government in Bangladesh

Rajshahi University, Bangladesh

INTRODUCTION

The Constitution of Bangladesh guarantees equality before the law to all its citizens and prohibits all forms of discrimination through articles 10, 27, 28, & 29 (Ministry of Law, Justice and Parliamentary Affairs [MOLJA], 2010). Accordingly, the Government of Bangladesh [GOB] has adopted several initiatives for the empowerment of women. The GOB declared the first National Policy on Women's Advancement on March 08, 1997 encompassing all the different aspects of women's lives. Additionally, the GOB signed the Convention on the Elimination of all Forms of Discrimination Against Women (CEDAW), Beijing Platform for Action, the Millennium Development Goals (MDGs), and the Convention on the Political Rights of Women for the advancement of women (Ministry of Women and Children Affairs [MOWCA], 2011).

The efforts of the government to empower women have been quite effective. The country has achieved commendable advancement regarding women's participation in the areas of education, health, employment, and income. The global gender gap report 2018 ranks Bangladesh 48 considering economic participation and opportunity; educational attainment; health and survival; and political empowerment between men and women. This country also ranks 5th considering the political empowerment of women (World Economic Forum, 2018). Nevertheless, a huge gender gap is prevalent in every sector of life including politics.

METHODOLOGY

This study tries to explore the status of women as elected representatives in urban local government and to identify the barriers to their participation as candidates and elected members. A qualitative methodological approach was employed to understand these barriers in the context of wider socio-economic, political, and cultural contexts. Primary data for the study was collected through semi-structured face-to-face interviews with 25 elected female representatives from two City Corporations and two Pourashavas. The researcher intended to arrange an interview with participants from diverse backgrounds. Accordingly, participants were selected considering their length of service as elected representatives (both first-timer and at least with experience of serving the office for two terms), nature of constituency (general ward or reserved) and party affiliation (Awami League, Bangladesh Nationalist Party, Jatiya Party or other).

Secondary data for this research was collected from published and or unpublished materials, books, journals, reports, newspapers, basic legal documents, and government policy papers relevant to the study and from the Internet. The researcher used secondary data to support and complement primary findings.

DOI: 10.4018/978-1-7998-3473-1.ch066

The interview questions were designed into two sections: first part intended to collect background information like age, education, and occupation of the participants while the second to extract information about their involvement in politics, party membership, experience in political office and the barriers. The whole interview sessions were audio recorded with consent from the participants. Initially, the interviews were conducted in the local language “Bangla” and afterwards were translated into English. Every participant was given a pseudonym so as not to disclose his or her identities. Responses to questions obtained from each participant were coded in the same category to enable deeper analysis of those responses. Then data was coded into analytical units. A relationship between data and variables was established by interpreting statements arranged in terms of similarities and dissimilarities. The data was analyzed by organizing it into different categories based on themes, concepts, and similarities. Results were presented through narrative text, simple computations, and analytical reasoning.

POLITICAL SYSTEM IN BANGLADESH

Bangladesh is a South Asian Muslim-majority nation emerged as a sovereign state in 1971. Since independence, this country has been struggling to sustain democracy due to army intervention from time to time (1980-1990 & 2007-2008). A parliamentary form of government currently runs Bangladesh. The Parliament of Bangladesh is unicameral, comprising of 300 general constituencies and 50 reserved seats exclusively for women. Members are elected directly through the “first-past-the-post” system every five years (Jahan & Amundsen, 2012). The Awami League (AL), the Bangladesh Nationalist Party (BNP), the Jatiya Party (JP), and the Jamat-e-Islami (JI) are the major political parties. The 14th amendment of the constitution in 2004 introduced proportional distribution of women’s reserved seats among the parties represented in parliament giving up the earlier practice of electing all women in reserved seats by the majority party from its own members.

Local government is enshrined in the constitution (article 59.1) of Bangladesh. The central government covers legal, operational, and financial matters as well as control and supervise local government bodies. The local government bodies enjoy a certain level of operational autonomy; however, they are in no way self-governing. A patron-client relation exists between national and local government in Bangladesh (Siddiqui, 2005). Bangladesh mainly has two types of local government: rural and urban. Urban local governments are single-tiered and include 12 City Corporations and 319 Pourashavas (municipalities) while the rural local government has three tiers: 64 Zila (districts) Parishads, 491 Upazila Parishads (sub-districts), and 4,554 Union Parishads (the lowest tier of rural local government). In addition, there are three hill districts local Parishads to serve the ethnic minorities and others living in that region. According to the existing legislation, City Corporations and Pourashavas consist of mayor and councilors elected by the voters of the concerned locality every five years. Besides, there are one-third reserved seats for women to be elected by direct voting (GOB, 2018).

BACKGROUND OF THE STUDY

There have been many studies investigated women’s participation in Bangladesh rural local government especially highlighting on Union Parishad. For example, Khan and Ara (2016) studied the impact of the Local Government (Union Parishad) Second Amendment Act 1997 of Bangladesh on participation and empowerment of women at that level. They claimed that the law enabled women to enter into the

elective positions at Union Parishad. However, the women failed to raise their voices and influence the decisions due to lack of financial, educational and social resources.

Panday (2013) discussed the impact of a particular policy on the state of women's political participation in Bangladesh highlighting the Local Government (Union Parishads) (Second Amendment) Act of 1997. He focused on the context of reforming the Act and the role of the actors behind the reforms. He concluded that conservative attitudes in society made it difficult for women to act as political leaders. Nevertheless, the Act helped to change the traditional political culture gradually and opened the door for women in politics.

Begum (2012) examined the barriers to women's political participation highlighting on the loopholes and weaknesses of the Local Government (Union Parishad) Act 2009. She found the participation of women disappointing due to deep-rooted patriarchy. The elected female members were discriminated while trying to exercise their rights. The system of 'reservation' created an imbalanced power relation that resulted in disrespect for the elected women members and deprived them of participating in decision-making.

Islam and Islam (2012) studied the barriers to women's participation in local politics. They identified several socio-cultural, financial, and religious factors as impediments to women's participation in the decision-making process. Additionally, ambiguity regarding their roles in the law hindered their participation in Union Parishad.

Khan (2010) tried to explore the experiences of the elected women members in pursuing to establish their rights at the Union Parishad. He found that social norms and practices and patriarchal structure, in general, did not allow women to participate in politics.

Panday (2008) studied the impact of quota on women's political participation and claimed that the quotas had helped to increase their number in politics. However, their participation in the decision-making process was low, except for a few party leaders. In a comparative study focusing on the lowest tier of rural local government between Bangladesh and India, Panday (2006) found that despite the presence of affirmative actions in both countries, women were discriminated due to structural, religious, and cultural factors. Male politicians did not cordially accept them and/or allowed them to participate in the decision-making process at this level.

Khan and Ara (2006) in a study on women's participation and empowerment in rural local government in Bangladesh identified lack of operational guidelines for female elected representatives and discriminatory attitudes of the male members as impediments to their participation.

Conversely, scholarships on gender and urban local government in Bangladesh are few. Taskin (2015) investigated the status of female ward councilors elected to the reserved seats in Dhaka City Corporation. She identified non-cooperation from the male colleagues as a prime factor that hindered women's participation in the decision-making process in general, and more specifically, in the standing committee meetings.

Zaman (2012) asserted that male colleagues discriminated women councilors because of lack of specific laws regarding their roles. Additionally, family responsibility, economic dependence, lack of education, religious, cultural and social norms affected their participation in politics.

Moin (2011) tried to investigate the issues related to women's participation and empowerment in local government politics (urban and rural). She identified lack of male members' co-operation, lack of opportunity to express their own opinions, non-clarified responsibilities for women members, harassment by community people or male members as significant barriers.

In another comparative study on the nature and political empowerment of women between two urban local bodies, Zaman (2007) found that women were underrepresented and neglected due to lack of finance, lack of support from society and family, and male-dominated politics.

Hossain (2006) examined the functions of the female councilors and the obstacles they faced while performing their duties. He concluded that women councilors lack confidence and they were not given equal importance like the male councilors in the meetings and other city corporation activities.

Islam (2002) in her study identified urban local government office structure, socio-political, economic, legal, and psychological state of the country as hindrances to the work of women councilors in Bangladesh.

All these studies identified insufficient participation of women in local government politics. They have revealed that women are still marginalized compared with men at all levels of politics except as voters. However, most of the studies focused on rural local government. In addition, the studies were conducted when the local government election was non-political.

The Cabinet of Bangladesh approved amendments of the Local Government Acts and introduced partisan election for the mayor posts and non-partisan for councilors effective from October 2015 local elections (Democracy Watch, 2016; Nath, 2015). Elections took place at seven City Corporations and 234 Pourashavas after introducing the partisan system. This study is significant, as it will examine whether the new election system has improved the number of women as candidates and elected representatives in City Corporations and Pourashavas.

WOMEN IN POLITICAL PARTY STRUCTURE

Integration of women in the party structure is essential for their advancement and empowerment. It is a common practice by the political parties like the AL and the BNP to involve women workers and supporters for political campaigns, anti-government protests, demonstrations, and rallies. However, they are reluctant to promote potential female applicants as candidates and leaders in elections. Although all the parties have established branches or committees in recent years, women mostly hold feeble and non-influential decision-making positions in the central executive committees of the political parties in Bangladesh. Therefore, women have practically no voice in the decision-making process. The AL, BNP, and JP's central decision-making committees have only about 10%-12% female members while JI has none. Although female pioneers have directed both AL and BNP for over 30 years, the overall representation of women in the different hierarchical bodies of the two parties is inadequate (Ahmed, 2008; Jahan, 2014). Moreover, the parties lack specific strategies to meet the conditions imposed by the Bangladesh Election Commission (BEC) of attaining 33% women in all committees by 2020 (Jahan, 2014).

WOMEN IN NATIONAL POLITICS

Since 1990, women in Bangladesh are serving as head of the government and leader of the opposition. The Speaker at the national parliament and head of the Ministry of Education are women. However, women are far from achieving gender parity, specifically, in politics and decision-making areas. Bangladesh ranks 97 with 20.6% of women MPs in the parliament (Inter-Parliamentary Union [IPU], 2019). However, this ranking is done considering a total number of female MPs elected under quota and to the general constituencies (50 reserved seats and 22 as general seat MPs). The political parties nominate only a few female candidates to the general constituencies. Furthermore, the number of women elected

to the general constituencies has been very low ranges from 2%-3% to a peak of 7.3% in the 11th parliament (Jahan & Amundsen, 2012; IPU, 2019).

In the general election of 2018, only 3.49% was female candidates. The ruling party Awami League and its alliance nominated 22 women while the BNP, along with its alliance nominated 16 female candidates in 300 seats (Antara & Raju, 2018; Chowdhury, 2018). However, 7.33% of women candidates were elected. This result is consistent with those in the parliamentary election held in 2014 (4.9% of the total candidates were women and 6.7% of them were elected) and 2008 (4.1% of the total candidates were female and 8.3% of them elected) to the general constituencies (BEC, 2018; IPU, 2017). Therefore, it can be said that women are far behind men as candidates and elected representatives. It is mention worthy that women who are nominated to stand in the general constituencies have strong affiliations with the current leadership, or are wives/daughters of a late MP. An ordinary woman without such political connections will have to struggle a lot if she wants to make a career in politics due to the traditional nature of politics and patriarchal mindset in the society (Chowdhury, 2002).

WOMEN IN RURAL LOCAL GOVERNMENT

Although women have been entitled to exercise their voting rights in local elections since 1956, their participation at all levels of local government was limited. The Local Government ordinance 1976 first introduced the provision to include two nominated women members in Union Parishad in independent Bangladesh. The Local Government (Union Parishad) Ordinance 1983 increased the numbers of nominated female members to three. In 1993, the Local Government (Union Parishad) (Amendment) Act omitted the system of nomination and launched the system of indirect voting to elect three women to three reserved seats to be elected by the chair and members of the respective Union Parishad and dividing each Union Parishad into nine wards (Ahmed, Chowdhury, & Shefali, 2003). The Local Government (Union Parishad) Second Amendment Act of 1997 introduced the system of direct election to the reserved seats for women. Moreover, women may contest for any of the general constituencies and as chair (MOWCA, 2014). However, the participation of women at this level is frustrating; 23 women were elected as chairs in 1997 Union Parishad elections while 22 female chairs in 2011. In the general wards, the picture is similar; 24% of the elected members were women in 1997 while 13.8% women were elected in 2003 (Democracy Watch, 2014).

Additionally, the Upazila Parishad Act 2008 and 2009 reserve one seat for women between the two elected vice-chairs. As per the Local Government (City Corporation) Act 2009, one-third of the councilors' seats are reserved for female candidates, and women can contest in the general seats (MOWCA, 2014). In the 2009 Upazila election, 480 women were elected to the reserved post of vice-chairs. In addition, three women were elected directly as chair among 1,936 contestants. Some 167 women were also elected as councilors out of 3,703 seats through direct voting. However, women's participation dropped in the 2014 elections, in which a total of 1,507 women contested in 458 Upazilas (Democracy Watch, 2014) and only five women were elected as chairs (United News of Bangladesh [UNB], 2016).

WOMEN IN URBAN LOCAL GOVERNMENT

Participation of women in urban local government is more or less similar to their representation at other levels of politics. Before the Gazette notification (the Pourashava Ordinance 1977, amended in 1998,

and Gazette extra copy dated 22/3/1999) for Pourashavas and City Corporations respectively, women councilors were appointed by selection. The introduction of the indirect election in 1994 allowed women to participate in urban local government. Male commissioners in Dhaka City Corporation elected nineteen women councilors to the reserved seats in that year. Moreover, one female ward commissioner was directly elected in Dhaka City Corporation. In 1998, the ordinance was revised, and direct elections to the reserved seats were made obligatory to promote women's participation in urban local government. Furthermore, the amended ordinance announced that regardless of the number of ward commissioners in a Pourashava and City Corporation, one-third of the number of commissioner's seats should be reserved exclusively for women to be elected directly (Islam, 2002). However, the status of women in urban local government both as mayors and of councilors in the general constituencies remains insignificant.

In the history of Bangladesh, Dr Selina Hayat Ivy was the first woman elected as mayor in 2003 from Narayanganj Pourashava upgraded as City Corporation in 2011. She is serving the Corporation as mayor since then. Later on, another woman was elected as mayor in 2004 from Bakerganj Pourashava. In 2010-2013 elections of seven City Corporations, no woman was elected (BEC, 2018). In 2014, a woman, wife of slain Narayanganj City Corporation panel mayor and councilor Nazrul Islam, won the by-election as a general councilor that was previously occupied by her husband. It is mention worthy that she was defeated against a BNP nominated male candidate in the Narayanganj City Corporation Election 2016. Thus, it seems that she was elected because of her husband's image and sympathy from the voters (Karmakar, 2016; UNB, 2015).

Dhaka North, Dhaka South, and Chittagong City Corporation elections 2015 were non-partisan and male-dominated. Dhaka North City Corporation election 2015 witnessed 16 male candidates for the position of mayor with no female contestant, 289 men, and 11 women contestants to the general seats. In Dhaka South City Corporation election 2015, 20 male candidates and no female vied for mayor position while Chittagong City Corporation election 2015 had 12 men as mayor candidates with no female contestants (BEC, 2018).

Since 2016, local government elections are conducting on a partisan basis. However, the status of women candidates as mayor and general councilors has not changed. Major political parties like to nominate male candidates to these positions, as they are afraid of losing the seats by nominating female candidates. Therefore, Comilla and Rangpur City Corporation elections 2017, Gazipur, Khulna, Rajshahi and Barisal City Corporation elections 2018, all were male-dominated. Narayanganj City Corporation election 2016 was an exception as AL nominated Dr Selina Hayat Ivy as mayor candidate and she was elected (ibid). It is mention worthy that Dr Ivy is from a very reputed political family; her father was very close to AL and she has good reputations in the locality. Despite that, she found it difficult to get party support at the beginning. However, AL nominated no female candidates to vie in the general constituencies.

In Comilla City Corporation election two women (one from AL and one from Jatiya Samajtantrik Dal) contested as mayor; both were unsuccessful. Recently, another woman from Bangladesh Samajtantrik Dal vied for mayor position in the Barisal City Corporation election and failed. Two women contested to the general constituencies in the Narayanganj City Corporation election 2016 against 154 men; three female candidates vied in Rangpur City Corporation election 2017 against 207 males; one each in Rajshahi and Khulna City Corporation election 2018 contested for the general constituencies and all failed; all the female candidates contested as Independent or from minor parties. The number of women candidates as mayor and general councilors are almost nil or trivial like before (BEC, 2018).

Elections were held in 234 Pourashavas in November 2015 where 945 candidates (AL - 234; BNP - 223; JP - 74; Jashod - 21; Independent - 285; others - 108) contested for the mayor position. Among

945 candidates only 20 were women (seven by the AL, one by the BNP, three by the National People's Party and nine by other political parties). In the election, five female contestants withdrew their nominations and finally, 15 candidates vied as mayor and two of them won. Surprisingly, after launching partisan election, numbers of female candidates for the mayor position has dropped off significantly in 2015 compared to the 2011 election. In the 2011 Pourashava elections (217 Pourashavas), 26 women were indirectly supported by major political parties like AL and BNP while only eight women were supported by major political parties in 2015 election (Democracy Watch, 2016). In this election, only one woman was elected as mayor and two as general ward councilors against 216 male mayors and 1,951 male councilors (BEC, 2018).

This indicates that the introduction of partisan politics. has no impact on the participation of women at the urban local level. The parties play a dual character: they prefer and promote male candidates while delivering a lecture on the empowerment of women in public. Male leaders push aspirant female candidates toward the reserved seats. Traditionally, voters in Bangladesh cast their ballots for the party, not for the candidate. Mohsin (2004) claimed that political parties might minimize the number of female candidates because of the fear that people may not vote for their party if they have many female candidates. Therefore, Gender equality in politics is not possible until political parties and community change their attitudes towards women.

MAJOR BARRIERS TO POLITICAL PARTICIPATION OF WOMEN

Based on field data, the barriers to the political participation of women are categorized into three major groups: socio-economic barriers; political and institutional barriers; and socio-cultural and ideological barriers.

Socio-Economic Barriers

These barriers concern family responsibilities; lack of education and finance; and violence, harassment and lack of security. All the participants have identified the domestic role of women as one of the most critical barriers causing women's underrepresentation in politics. According to them, domestic responsibilities compel many women to stay away or join politics at a later stage when they become free from looking after the young children and elderly members.

According to a participant:

Lack of support from husband and in-laws is a major problem for women. I get up early in the morning and do the cooking, cleaning, and other stuff. Then I go to my political office. This way I manage my family, and politics. In addition, as I am living in an extended family, I get support from other members and my husband. However, many women do not have this opportunity.

As women mostly spend their times with children and/or senior members who barely have knowledge or interests in politics, they lack scope to discuss political affairs with people at home or with an outsider. Moreover, due to traditional rules and practices, husbands usually do not share domestic activities that keep women away from politics as Ahmed (2008), and Chowdhury (2009), and Zaman (2012) found.

The interviewees identified lack of education and specifically finance as significant barriers to their participation. A certain level of education is necessary for politics, as, without education, it is hard

to understand the rules and regulations. Although all participants have recognized the importance of education, only a few residing in City Corporation/ Pourashava had tertiary education. Majority of the participants had completed year/grade X-XII. This trend of education is consistent with the social system in Bangladesh. It is seen that a large number of girls in Bangladesh usually get married just after completing their primary or secondary education. After marriage, the majority of them fail to continue their studies due to non-cooperation from their husbands and in-laws. Moreover, many parents do not send their girls to high school due to financial insolvency as primary education is free and compulsory for all, but not so for high school. In addition, if a family has limited affordability, the preference is given to the male child (Sultana, 2012).

To vie in electoral politics, a certain amount of money is required that many women cannot avail as men often exercise control over financial resources (Ahmed, 2008; Chowdhury, 2009). Only six of the participants were engaged in the job sector while the rest were homemakers. All the participants received support from parental families, husbands, and in-laws to spend on the election campaign. It is evident that if the participants could not get the financial assistance they might find it quite difficult to participate in the election. A woman who is single or who does not have the support of their family members may find accessing financial support for their political careers extremely difficult in Bangladesh.

Regarding the importance of money, a councilor said:

Money is necessary for the election. Finance is required in the campaign; one needs to bear at least the cost of snacks and drinks for the supporters. In addition, strong finance helps to be less corrupt.

Another impediment to their participation is the ever-present threat of political violence and sexual assault in Bangladesh. Violence in society and politics act as a barrier for women who would like to make a career in politics. Furthermore, the lack of security discourages many eligible and interested women to join politics. A participant stated:

Lack of security is a major concern for elected women. Women face harassment both physically and verbally when going to work. Therefore, many women lack the courage to be in politics.

Politics is a 24-hour job that involves extensive travel and dealing with many people including strangers. A woman may be sexually harassed that may ruin her political career. Therefore, many women stay away or give up politics (Chowdhury, 2009; Huda, 2003).

Political and Institutional Barriers

Politics has long been dominated and controlled by men around the world. In Bangladesh, politics is dominated and controlled by men that have resulted in lower interest and involvement of women in politics. The participants identified politics as a place of conflict and confrontation that many women are afraid of and stay away. In addition, lack of party support and political network act as hindrances to them. Moreover, rampant corruption, poor governance, and political strikes jeopardize democratic stability and impede their political participation. According to a participant:

Politics is full of conflict and unfair competition. In addition, muscle and money are the two main elements of politics. Women usually do not have either of these. Furthermore, vote buying is a common practice in the elections. The political environment, the image of political leaders, rampant corruption all discourage women to get involved here.

The participants identified political parties' role towards women as a barrier to their political participation. The most significant barrier is the candidate nomination process to the general wards. Male

politicians do not like to select a female candidate to vie as a general ward councilor or mayor. They always prefer women to contest as reserved seat representatives. However, being nominated as a reserved seat candidate is not an easy task as male politicians make the selection. A participant expressed her opinion as:

It is difficult for women to get a nomination from the party. The male politicians possess negative attitudes towards women and show superiority over. They are not interested in giving space to women. Overall, male politicians are not supportive. It is difficult for women without a strong political network to get a nomination from the party.

All participants in this study have relatives like male councilors, MPs, or powerful political party leaders who helped them to get a nomination. It needs to mention that all the participants except two contested as reserved seat councillors.

In addition, another problem is participation in council meetings. In most of the City Corporations and Pourashavas, meetings are mostly male-dominated and women find it difficult to express their opinion. Narayanganj City Corporation is an exception. A female mayor runs this urban local government body; she is highly educated, experienced, and politically strong and influential. The mayor always encourages female councilors to participate actively in meetings and other corporation activities. In other urban local government bodies, male councilors, in general, underestimate female councilors; humiliate, and criticize them whenever they attempt to give an opinion. This type of incidents takes place due to ambiguities in the ordinances regarding the roles and responsibilities of the reserved seat councilors.

Socio-Cultural and Ideological Barriers

Cultural norms have significant impacts on women in Bangladesh. The popular tradition portrays women as physically weak and intellectually inferior requiring continuous protection of the physically strong and intelligent men (Islam, 2000). Most of the norms and values that are related to the structure of Bangladeshi society are gendered and usually support masculinity directly or indirectly. This social system upholds a rigid division of labor that controls women's mobility, roles, and sexuality (ADB, 2001). Participants identified the patriarchy, traditional division of labor, peoples' attitudes towards women in society, and the socialization of girls and women, in particular as the most serious socio-cultural and ideological barriers to the political participation of women.

All the participants recognized patriarchy as a critical issue to their advancement in politics. The traditional society is saturated with patriarchal values and norms where women are seen as subordinate and dependent on men. An unequal power structure exists in the family and wider society that favors the supremacy of men in decision-making. Moreover, men have strong reservation regarding women in leadership and management positions as Ahmed (2008) and Halder (2004) previously found. A participant stated:

Men, in general, do not accept women in politics. They mocked us during our election campaign. They show neglecting attitudes towards women. They think politics is their domain. In many ways, they try to create obstructions so that we cannot participate in politics.

In addition, the socialization process in the family and society develop girl and women in such a way that they lack the confidence to take a leading role in politics. Furthermore, Similarly, the participants

identified attitudes of society towards women's primary roles as mothers and homemakers as an obstacle to their political participation as another participant stated:

The gender division of labor creates extra pressure on women and compels women to stay away from politics due to time crisis. Men in our society, except a few, are not yet mentally ready to work with women in public spheres especially in politics. Patriarchy, male-domination, ideology, influence women's participation in politics largely.

Furthermore, they recognized religious customs as an impediment that restrict their autonomy in various ways. Likewise, Halder (2004) found that due to religious customs people in Bangladesh, in general, prefer women stay within the domestic spheres; women need to maintain a certain dress code, they are deprived of property rights that impede their entry into politics.

RECOMMENDATIONS

In Bangladesh, a number of factors restrict women's participation in urban local government politics. It is not that they are incapable; it is due to the systems that discourage them from participating. Political parties have a major role in ensuring gender equality in politics. The most difficult challenge for women is to get a nomination from the male-dominated political parties. In addition, women usually are less confident to vie against men in leadership positions. The political parties can play a key role by recruiting more women through encouraging, supporting, training, and mentoring young women. The government may adopt special laws to ensure that 50% of candidates as mayor and general councilors are women in the local government election.

Women lack access to higher education due to socio-economic reasons. The government may arrange free and compulsory education for women up to high school (year XII). Awareness building and attitude change towards the traditional roles of women also need to take place through mass media and campaigning.

Lack of finance impedes the political participation of women. The GOB has doubled the amount of honorarium effective from July 2017 for local government representatives (Bhattacharjee & Molla, 2017). However, the amount is not adequate for councilors of the small Pourashavas. Therefore, the government may establish a common fund to assist female candidates to meet the election expenditure.

Harassment, bullying, sexual harassment, lack of security keep many aspirant women away from politics. The GOB needs to strengthen and revise the existing laws to mitigate workplace harassment and violence against women.

The local government ordinances and acts clearly defined the roles and responsibilities for the general ward commissioners. However, there is no specific responsibility mentioned for reserved seat commissioners. From a legal point of view, local government councilors in the reserved seats enjoy similar rights, opportunities, and privileges as local government representatives elected to the general wards. However, there are marked differences in terms of status and barriers due to different electoral systems and processes. Women reserved seat candidates and councilors for local government elections (City Corporation and Pourashava) have electorates three times larger than their general seat counterparts. The reserved seat systems in Bangladesh are designed in such a way that there is a separate women-only tier, which results in overlapping mandates for reserved and general seat holders (Paasilinna, 2016). The

roles and functions of the reserved seats need to be clarified so that women councilors elected in the reserved seats do not face any difficulties or harassment while performing their duties.

In addition, women are discriminated during the candidate selection process by male politicians on the ground that they have scope to take part in politics through reserved seats. Bangladesh Election Commission needs to revise the Political Party Registration Regulations 2008 to ensure equitable participation of women as general seat candidates and leaders in urban local government. It seems that political parties do not take the RPO instruction seriously, as there is no mention of any disciplinary actions against failure to achieve the target. BEC can impose a penalty for disobeying the RPO. It is necessary to ensure more female candidates as general ward representatives and mayor. The Election Commission may introduce separate wards for women ward commissioners so that they will have a certain area under their jurisdiction to be managed solely by them.

CONCLUSION

Participation of women in urban local government bodies is still negligible due to a complex interplay of socio-economic, political, institutional, and cultural factors. Women are discriminated during candidate selection process in election time and in the party organizations. A critical mass (30%) of women is necessary to bring change in their status. However, ensuring 30% of women as candidates, members of the party organizations or elected representatives seem quite difficult due to political parties' reluctance to implement RPO accordingly.

The provision of reserved seats has only increased the number of women in urban local government; it has no substantive impact to increase the quality of their participation as male politicians occupy the key positions (mayor and general ward councilors). Patriarchy is deep-rooted in the society that shapes and guides the political party leaders' mindset. Therefore, they treat women as 'ornamental' not as 'equal partner.' It is a good sign that women are coming forward by breaking conventional social norms and practices and participating in politics. The leaders of political parties may play a major role by promoting women agenda as well as recruiting more women in politics. The government, NGOs, civil society groups and women organizations may work in collaboration to guide and assist the interested and potential female candidates to overcome the barriers to their participation in politics.

FUTURE RESEARCH

The study deals with elected female urban local government representatives. Future study may be conducted on the unsuccessful female candidates to know their reasons for failure. In addition, a study on interested women who want to join politics can give important insights regarding their reason to join and knowledge about politics. A study on male mayors and ward commissioners' opinions regarding female councilors elected to the reserved seats may provide new ideas while adopting new programs and strategies for the advancement of women in politics. Further, a comparative study on urban and rural local women representatives to explore their problems will provide new insights.

KEY TERMS AND DEFINITIONS

Hill Districts Local Parishads: The three Hill District (Rangamati, Khagrachhari, and Bandarban) Local Government Parishads were created in 1989 to grant autonomy to the ethnic minorities living in this region. The chairs of the three Hill District Local Government Parishads are elected from among the tribal people.

Representation of the People Order (RPO): In 2008, GOB gave instruction to all the political parties registered with the Bangladesh Election Commission (BEC) to ensure at least 33% women representation in all committees by 2020.

Reserved Seats: Reserved seats keep a specific number of seats for women in a parliament or local body, mentioned in the constitution or by laws. The Government of Bangladesh (GOB) reserves a quota for women in the national legislature to secure their participation. At first, there was a quota of 15 reserved seats for 10 years. Afterwards, the GOB increased the quota to 30 in 1990, to 45 in 2004, and finally, fixed at 50 in 2011. There is also a provision of one-third seat reservation for women in local government.

Union Parishad: It consists of a chair, nine general councilors and three women councilors from three reserved seats. The chair and all the members – including women members holding reserved seats – are directly elected for five years.

Upazila Parishad: It consists of a directly elected chair, one male and one female vice-chair, representative members, female members in reserved seats, and official members. The representative members are the Upazila Parishad chairs and Pourashava mayors of each Upazila. All heads of government departments working in the Upazila are ex-officio members without voting rights.

Zila Parishad: It consists of a chair, 15 open seats, and five additional women's reserved seats. An electoral college elects the chair and the members.

INTRODUCTION

According to the definition adopted by the International Organization for Standardization (ISO) a standard is a document, “established by consensus and approved by a recognized body, that provides, for common and repeated use, rules, guidelines or characteristics for activities or their results, aimed at the achievement of the optimum degree of order in a given context” [ISO, 2015]. The fact that standards are established ‘by consensus’¹ distinguishes them from legislation. Typically, the use of standards is voluntary. However, through legislation they may become mandatory (e.g. many health and safety standards) or ‘quasi-mandatory’ (e.g. Harmonized European Standards).

Standards – in a very general sense – have been with humankind for quite some time. About 4,000 years ago the first alphabets emerged, enabling new forms of communication and information storage. Around the 7th century BC the Lydians invented the first coin-based currency; it established the basis for easier inter-regional trading. The advent of the railroad in the 19th century resulted in a need for technical standards, e.g. those that enabled compatibility between individual parts of technical artifacts, defining e.g. the width of railway gauges, the diameter of screws, etc. This was once more reinforced when mass production generated a demand for interchangeable parts. In parallel, the invention of the electric telegraph in 1837 triggered the development of standards in the field of electrical communication technology. In 1865, the International Telegraph Union – to become the International Telecommunication Union² (ITU) in 1932 – was founded by twenty nation states. The other major international standards setting bodies, the International Electrotechnical Commission (IEC) and ISO, were founded in 1906 and 1947, respectively.

In the field of Information and Communication Technologies (ICT) international standards are the major mechanism to ensure interoperability between systems. Frequently, ICT standards also describe a commonly agreed platform upon which innovations can be based. Moreover, standards in general are a valuable means of technology transfer. They have also been used as policy tools – for example, they are a major pillar of the European Single Market. Standards’ potential economic implications must also not be under-estimated. A new standard may be used to extend a market, or even help open up a new one. Intellectual Property Rights (IPR), mostly patents, also play a major role here. That is, standards must also be considered as strategic tools for firms.

The above suggests that standards are not just technical documents but that they may have ramifications well beyond technology. Accordingly, they should no longer be considered as pure ‘public goods’, i.e. as something that is non-rival and non-excludable [Deneulin & Townsend, 2007]. Rather, these days standards are typically seen as impure public goods, or club goods; they are non-rival and excludable, just like e.g. satellite TV, cinemas or private parks (see also e.g. [Hawkins, 2009]). This is largely due to the frequent incorporation of IPR into standards.

Against this background, this chapter will first briefly look at the links between standards and standardization, innovation and economics. It will then offer a brief description of the complex ‘web’ of

DOI: 10.4018/978-1-7998-3473-1.ch067

Standards Setting Organizations (SSOs) in the ICT sector. Subsequently, a flexible tool to describe the characteristics of an SSO will be discussed. It can be deployed by firms to identify the SSO that is best suited for a planned standardization activity. This will be followed by the description of a typical standards setting process. These are only parts of the fairly complex task of standardization management, which will be described next. The subsequent section will briefly discuss national standardization strategies. Finally, some likely future research directions are sketched.

BACKGROUND

Some Brief Economical Aspects

Not so long ago standardization and innovation were considered as almost mutually exclusive (see e.g. [Hemenway, 1975], reported in [Farrell & Saloner, 1985]). This has changed by now. In fact, close links between standardization and innovation may often be identified. Today, standardization is no longer considered an impediment to innovation. However, the unqualified claim that ‘standards foster innovation’ does not fully reflect reality either. Swann & Lambert [2010] observe that standards do both – enable and constrain innovation – but that the enabling aspect is much more important. Specifically, they note that “... *standardization does constrain activities but in doing so creates an infrastructure to help trade and subsequent innovation. Standardization is not just about limiting variety by defining norms for given technologies in given markets. Standardization helps to achieve credibility, focus and critical mass in markets for new technologies*” (p. 370).

That is, especially in the field of ICT many standards describe a commonly agreed platform upon which innovations can be based and marketed. Accordingly, standards may be, and indeed are, used as strategic tools. For example, a new standard can extend a market, or even help open up a whole new one (just think what GSM did for mobile communication). On the other hand, backing and subsequently being locked into a ‘wrong’ technology (i.e. one that does not get standardized) may well ruin at least smaller companies.

What’s more, “*Standards are not only technical questions. They determine the technology that will implement the Information Society, and consequently the way in which industry, users, consumers and administrations will benefit from it*” [CEC, 1996; p. 1]. That is, those that develop ICT standards today at the same time shape much of the ICT environment we all will use in the future. And if they do their job properly, i.e. if they develop standards that meet the needs of all stakeholders (including e.g. individuals, communities, businesses, and governments) society at large stands to benefit.

From a macro-economic perspective, DIN [2004] finds that “*standardization contributes to GDP growth at the rate of about one percentage point per annum*”. This is in line with a number of similar studies from other countries. Blind [2013] reports that the contribution of standards to the growth rate in different countries was equivalent to 0.9% in Germany, 0.8% in France and Australia, 0.3% in the UK and 0.2% in Canada. Adopting a micro-economic perspective, ISO [2011, 2012] did a number of studies in companies from different business and countries. Based on Porter’s value chain [Porter & Kramer, 2011] these studies show that the implementation of standards can provide economic benefits to firms between 0.5% and 4% of their annual revenues.

By now, participation in standards setting has become a major strategic tool for many firms. Frequently, a firm’s aim will be to influence the process for its own benefit. This holds particularly – though by no means exclusively – for large companies. Other potential motivations include e.g. networking, intelligence

Figure 1. The ICT Standardization Universe in the 1970s (adapted from [Jakobs & Kritzner, 2009]).

gathering and increasing credibility (see e.g. [Jakobs, 2013]). In addition, standards are a valuable means of technology transfer, which makes them also relevant also for academia and research institutions. Standardization also provides a legal platform for co-operation with competitors and (potential) customers.

SETTING ICT STANDARDS

The ICT ‘Standardization Universe’

Back in the 1970s, the standardization universe was still rather simple and well-structured. Telecommunications standards (called ‘Recommendations’) were developed by the Consultative Committee for International Telephony and Telegraphy (CCITT; the predecessor to ITU-T), a then quasi-monopoly UN organization. This sector was almost completely separate from IT standardization, which was lead by ISO and its national member organizations. That is, standards were almost exclusively set by ‘formal’ SDOs (Standards Developing Organizations; i.e. those with some sort of official legitimation, such as ITU or ISO). The one private consortium in existence was the European Computer Manufacturers Association (ECMA). Figure 1 depicts this situation.

These days, an extensive web of Standards Setting Organizations³ (SSOs) are active at the international (e.g. ISO and ITU), the regional (e.g. the European Telecommunications Standards Institute, ETSI) and the national level (e.g. the American National Standards Institute, ANSI; see Figure 2). Their output is frequently referred to as ‘de-jure’ standards, although these standards do not have any regulatory power per-se. In parallel, a plethora of private industry fora and consortia (a couple of hundred), such as the World Wide Web Consortium (W3C) and the Open Mobile Alliance (OMA), produce what is often termed ‘de-facto’ standards. The processes through which both types of standards are developed are typically very similar (see below). The required level of consensus may differ, though. It should be noted that both ‘de-facto’ and ‘de-jure’ standards may gain some regulatory power, e.g. through references in legal documents.

Figure 2. The ICT Standardization Universe Today (excerpt; adapted from [Jakobs & Kritzner, 2009]).

Figure 2 also shows that the former clear-cut distinction between Information Technology on the one hand and the Telecommunication sector on the other has largely disappeared. This reflects the situation in the market, where the two sectors are hardly distinguishable any more (virtually every computer can communicate and every smart phone is also a small computer).

This highly complex structure has led to a considerable degree of fragmentation. Frequently, several SSOs are active in similar or overlapping domains. As a result, there may well be competition either generally between SSOs that cover similar ground or temporarily between different SSOs' Working Groups working on similar projects. Consequently, there is an urgent need for co-ordination. Given the diverse nature of the individual SSOs (see also below) this may be extremely difficult to achieve.

Nevertheless, a comparably high level of coordination exists between ISO and the regional and national SDOs, to avoid inconsistencies and contradictions between international, regional and national standards. This coordination is based on the WTO's agreement on 'Technical Barriers to Trade' [WTO, 2015]. In a nutshell, it states that national bodies shall use international standards and remove contradicting national ones whenever possible. Figure 3 shows different types of bi-lateral agreements.

Following a different approach, the Global Standards Collaboration (GSC; see Fig. 2) provides for the regular exchange of work programs and other information between its members, the regional Telecommunication standards bodies and the ITU. ETSI Partnership Projects represent a related approach

Figure 3. Different Types of Bi-lateral Agreements Between SSOs (adapted from [Jakobs, 2013]).

to co-ordination. These projects coordinate groups of regional SDOs working towards a common goal. 3GPP⁴, which is active in the field of wireless communication, is a prominent example.

Coordination of the activities of consortia working in overlapping fields is not always desired; some consortia were primarily established to compete with others. Where this is not the case, cooperation is in most cases based on different types of bilateral liaison agreements. These agreements are, in most cases, either rather generic (e.g. a general Memorandum of Understanding) or very specific (e.g. relating to one specific standard). Overall, cooperation between consortia is not nearly as pronounced as between SDOs.

The Standards Setting Organizations (SSOs)

The characteristics of individual SSOs may differ considerably, in various respects. This holds for both SDOs and consortia. Therefore, the traditional distinction between these groups is not overly helpful. A more flexible and meaningful approach was introduced by Updegrove [2006]. It is based on a set of attributes that can be applied to describe an SSO. These attributes fall into four categories:

- General
- Membership
- Standards setting process
- Output

An attribute is a tuple <type, value>. Table 1 summarizes the defined types and provides a brief description for each; the values need to be determined individually for each SSO.

Table 1. SSOs' Attributes and Descriptions (taken from [Jakobs & Kritzner, 2009]).

General Internal	Description
overall goals business models	These provide some general background information.
governance	'Governance' is important for those who wish to influence the goals and activities.
finances staffing	'Finances' and 'staffing' are important to evaluate the chances of an SSB's long-term survival.
IPR policy	IPR policy should not deter any stakeholders.
External	
reputation	Joining an SSO with a poor reputation, or with a poor record, will not make too much sense in many cases.
competition	Do competing SSOs exist, or are they likely to emerge in the near future?
liaisons	Is the SSO prepared to co-operate with other entities?
Membership	Description
Quantitative: • overall # of members • membership levels • membership fees	Provides some information about the relevance of the SSO. In many cases, some are more equal than others. Who decides, who does the work, and are these the same? May also help to determine a prospective new member's chances of active contribution and decision.
Qualitative: • key players involved? • 'active' members • individuals' capacity	Are those organizations important in the specific sector on board? Which are missing? Which members are prepared to invest resources into activities like e.g. editing documents, leading WGs, etc.? Is there a 'corporate whip', or do reps decide independently? What are the SSO's rules?
Standards setting processes	Description
Timing: • time for TC/WG establishment, • average time until finalization	Indicates the effort/time required to finalize a new standards project. Helps to determine whether or not a (perceived) window of opportunity can be met.
Process characteristics: • openness • transparency • required level of consensus • observation of due process • decision mechanism	Basically to determine how fair the process is? Do I have a say, or do the big guys determine? Can I complain, and to whom? Etc.
Beyond standardization: • implementations required? • proof of interoperability required • conformance testing	Indicate a more 'praxis-oriented' approach; crucial if products/services are to hit the market pretty soon.
Output	Description
Types of 'products'	Do an SSO's deliverables suit my needs? I do not always need a full blown standard, and may be prepared to swap consensus for speed.
Quantitative aspects: • standards output • # of implementations	Do they actually produce standards that are widely implemented? Indicates importance of output; if nobody implements the standards participation is hardly worth the effort.
Dissemination: • PAS submitter? • specifications for free?	Related to 'liaisons' above. Is an SSO prepared to bring its specifications into the public domain? And are they prepared to do it for free?
Follow-up activities: • standards maintenance • impact considered? • consistency checks in place?	How does an SSOs react to changes in technology/ requirements? And to errors/inaccuracies? Do they reflect on what they are doing? Are standards checked for consistency with others?

An SSO's IPR policy is probably the single most important criterion. In principle, each party that contributes to the work of an SSO on a specific standard is required not only to disclose any IPR that is relevant for this standard, but also to license it. This holds particularly (though not exclusively) for any 'Standards Essential Patents' (SEPs). If a standard cannot be implemented without infringing a patent this patent is called an SEP. Under the 'Royalty Free' (RF) regime licenses for such patents have to be granted for free⁵. Under a '(Fair), Reasonable and Non-Discriminatory' (F)RAND regime the IPR holder may ask for licensing fees⁶. The SSO does not normally interfere with the negotiations between the IPR holder and the potential licensee(s). No generally accepted definition or algorithm for the calculation of FRAND exists and the courts are frequently called upon to settle disputes (see e.g. [Updegrove, 2013]).

The Standardization Process

In general, the standardization process should make sure that its outcome (i.e. the standards) meets the needs of as many groups of stakeholders as possible. To come at least close to this goal, the World Trade Organization (WTO) has defined a set of "... *principles and procedures that should be observed, when international standards ... are elaborated ...*" [WTO, 2015]. Specifically, these include transparency, openness, impartiality and consensus, effectiveness and relevance, coherence and to address the concerns of developing countries. Most major SSOs more or less observe these principles although formally they are only relevant for national and international SDOs.

Terminology, procedural and structural details may differ⁷, but all major SSOs have adopted a standardization process that is subdivided into several stages. Table 2 exemplary summarizes the stages of the ISO/IEC process. Once a new Work Item has been agreed upon, a Working Group (WG; either an existing one or a newly created one) is charged with the development of the associated standard. When the WG has agreed upon a draft specification the members of the parent Technical Committee or Subcommittee (TC/SC) need to reach consensus. Depending on the number and nature of comments received the specification may be returned to the originating WG for further elaboration. Eventually, a vote will be cast at TC/SC level. If the approval criteria (in terms of majority and number of negative votes) are not met a revised version will be produced. The latter two steps may differ between SSOs and may have several iterations.

Table 2. Project stages and associated documents in the ISO/IEC process (taken from [ISO, 2015]).

Project stage	Associated document	
	Name	Abbreviation
Preliminary stage	Preliminary Work Item	PWI
Proposal stage	New Work Item Proposal ^a	NP
Preparatory stage	Working Draft(s) ^a	WD
Committee stage	Committee Draft(s) ^a	CD
Enquiry stage	Enquiry Draft ^b	ISO/DISIEC/CDV
Approval stage	Final Draft International Standard ^c	FDIS
Publication stage	International Standard	ISO, IEC or ISO/IEC
a	These stages may be omitted.	
b	Draft International Standard in ISO, committee draft for vote in IEC.	
c	May be omitted.	

It should once more be highlighted that virtually all SSOs follow a variation of this process⁸.

Not unlike the processes, the organizational structures of major SSOs are similar. In most cases both their technical work and their internal organization are hierarchically structured. Figures 4 and 5 exemplary show ISO's governance and work structure, respectively.

Figure 4. ISO's Governance Structure

Figure 5. ISO's Work Structure

Typically, a TC covers a rather broad field. For example, ISO/IEC's Joint Technical Committee 1's (JTC 1) scope is 'Information Technology'. It is subdivided into 20 Subcommittees (SCs). Each Sub-committee, in turn, may comprise a number of Working Groups (WGs; more than 100 in total in JTC1). This is where the bulk of the actual technical work is done⁹. The more strategic decisions are normally taken at SC/TC level. This is also where the decisive voting is done.

Managing Corporate Standardization

Standardization management refers to the set of activities a firm needs to perform in order to achieve its goal(s) in standards setting. That is, it needs to be clear about these goals in the first place. In many cases, standardization will be used as a tool to support a firm's business strategy in a given sector. To this end, standards setting activities and the business strategy need to be aligned. Potential activities in standardization may range from simple intelligence gathering via pro-actively starting standardization initiatives to the foundation of a dedicated standards consortium to develop and promote standards for a particular field.

Once these corporate goals are clear, a number of factors need to be taken into account, including.

- The (potentially) relevant legal, moral, ethical, societal boundary conditions.
- The characteristics of the individual SSOs and the links that exist between them (see above). Here as well IPR issues will play a major role in many cases.
- The obvious allies and opponents that will also participate and their technical and strategic interests.
- Potential alliances that could be formed based on similar/complementing interests..
- The nature of the contributions to be made (e.g. technical, requirements, editorial).
- The content of the contributions.
- The size of the team, the roles and the necessary capabilities of its members.

The latter point is frequently ignored. However, at the end of the day standards are developed by a group people who may cooperate or compete in a WG. These people's capabilities, backgrounds, views and agendas will to a considerable degree shape the final standard (see e.g. [Isaak, 2007], [Jakobs, 2011]). It should be noted that in addition to their technical expertise these people also need to be good communicators with a reasonable level of diplomatic and negotiation skills. It is, however, not always clear up-front whether or not they will actually act in the best interest of their respective employer [Jakobs, 2011]. Not least because of this uncertainty the selection of representatives with suitable expertise and experience and their briefing is a managerial issue whose importance should not be under-estimated.

Figure 6 summarizes and illustrates the different factors that need to be taken into account in corporate standardization management (without claiming completeness).

National Standardization Strategies

Not only firms have realized the importance of standards. Almost all industrialized nation states now have developed their own national standardization strategy¹⁰. Typically, standards are seen as important for the economy, policy making and societal issues. A typical statement reads "*Standards are a fundamental building block for the economy and society*" [NSSF, 2003, p. 4]).

Almost all national strategies highlight the increasing globalization of markets and the resulting equally increasing need for globally valid, unique and accepted standards. At the same time, they also aim to provide a competitive advantage for the respective national firms and to strengthen the respective national position in the global market.

A number of other aspects may also be found in most national strategies. These include, for instance, the links between research, innovation and standardization. Along similar lines, they highlight the role of standards as a vehicle for the transport of innovations to the market as well as for the convergence of

Figure 6. Some Factors that Influence Standards Development (based on [Jakobs, 2013]).

technologies (e.g. broadcasting, telecommunications and IT). The support of adequate education about standardization is another goal. This holds for both formal curricula and training on the job.

To achieve these goals, the need for an adequate national standardization infrastructure is stressed. This also includes the adaptation of current processes to shorter product life cycles and increasing consumer requirements. Specifically, the need for adequate (public) funding of the standardization infrastructure is also highlighted, not least in the light of the economic importance of standards.

Despite these similarities a number of differences between national strategies may also be identified. For one, the special needs and requirements of Small and Medium-sized Enterprises (SMEs) are only addressed in the strategies of the European countries. And while all strategies aim to improve the national performance in globalized markets the US strategy quite openly aims to ‘export’ its sector-based national standardization system, not least to counter the export of European technology and practices to other nations through the European standards processes. The Chinese strategy is the only one that explicitly highlights ICT. ‘Next Generation Information Technology Industry’ is the second of the 13 major areas identified where science and technology shall support the development of new technical standards. The support of R&D (Research and Development) for standardization is another focus of the strategy, an aspect the other strategies only touch upon.

FUTURE RESEARCH DIRECTIONS

Despite standards’ long history ‘Standards and standardization’ is a fairly new research topic. Initially, the economic dimension of standards attracted researchers’ interest (see e.g. [David & Greenstein, 1990]). Eventually, other topics emerged, including e.g. legal problems (e.g. Intellectual Property Rights, IPR), policy aspects (e.g. standards as policy tools), stakeholder-related issues (e.g. stakeholder influence, process credibility, etc.), corporate standardization management and many others. De Vries et al. [2018] present a (probably slightly biased) overview of what researchers in the field see as major future research topics.

In the following the impact that emergence of smart systems (e.g. the Smart Grid, Smart Manufacturing, Intelligent Transport Systems, Smart Homes and Smart Cities) may have on the world of standards setting will be discussed in a bit more detail.

Smart systems are a comparably recent trend that is increasingly gathering momentum. The ‘smartness’ is the result of the integration of Information and Communication Technology (ICT) into ‘traditional’ technologies, thus providing them with advanced control and amenability functions previously available only in the virtual world. To offer the user smart applications, these systems need a communication infrastructure which, in turn, will typically be based on the Internet of Things (IoT). Forecasts indicate about 24 billion IoT devices for the year 2030¹¹.

Basically, the standardization of smart systems faces two major problems. One is the (technical) multi-disciplinarity of the task, the second, related one is the urgent need to also include a range of societal stakeholders; this is primarily due to the sheer ubiquity of such systems and the societal, environmental and economic ramifications this ubiquity causes.

Technical Multi-Disciplinarity in Standardization

The standardization of smart systems requires the co-operation of different technical disciplines. Table 3 below shows (some of) the technical disciplines that contribute to individual smart applications.

This multi-disciplinarity represents a considerable problem for standards setting. Traditionally, either one (occasionally several) Technical Committee (TC) covers one field. While close links exist between some TCs, co-operation in general is not overly well developed (see above). Moreover, these

Table 3. Sample Disciplines Contributing to Smart Applications

Smart Manufacturing	Intelligent Transport Systems	Smart Grid	Smart Buildings	e-Health
Production Engineering, Computer Science, Robotics Control Engineering, Telecommunication	Transport Telematics, Traffic Engineering, Power Engineering, Automotive Computer Science, Telecommunication	Power Engineering, Computer Science, Telecommunication	Architecture, Civil Engineering, Computer Science, Telecommunication	Medicine, Computer Science, Mechanical Engineering, Robotics, Telecommunication

smart applications will require co-operation between both standardization entities and individuals with very different cultures coming from equally different backgrounds. Plus, very different technology life cycles will need to be aligned somehow (speed has always been a major issue in ICT standardization, not so much in e.g. mechanical engineering). On top of that, applications like e-health and smart cities need to address issues of information security and safety and of trust, which adds yet another dimension and increases the complexity of the task. If and how the current standardization system can successfully address these issues or if any changes need to be made and if so, which ones remain open issues.

Smart and Responsible Standardization

Billions of sensors will collect data and make them available for smart applications and their users. A considerable part of this data will be personal or private. Moreover, the results of the analysis of this massive amount of data may have major e.g. economic, environmental and societal ramifications and directly impact citizens and businesses alike. Accordingly, potentially severe policy, societal, economic and even ethical issues need to be addressed in the development of smart systems. To be able to actually do so it will be necessary to integrate these aspects into smart systems' design as early as possible (not unlike the 'privacy by design' approach; see e.g.. [Langheinrich, 2001]).

In a way, a smart city represents a superset of the other smart applications. Figure 7 shows a popular model of a smart city. On the one hand, this model shows that a number of other smart applications contribute to the objectives of smart cities. On the other hand, it highlights the relevance of a smart (ICT) infrastructure as the basis of a smart city.

Figure 7. Smart city model according to and adapted from Navigant [2011]

For each layer, dedicated standards (or best practices) will be needed. Today, almost all standards for smart systems address the communication infrastructure level. At this level, standards almost exclusively deal with purely technical aspects and are thus less complex to develop (plus, many of these standards pre-date smart systems and only need to be incorporated).

Standards for the ‘smart policies and objectives’ layer will provide guidance to (city) leadership for the development of an overall strategy, the identification of priorities, the development of a practical implementation roadmap and for an effective approach to monitoring and evaluating progress. Accordingly, most non-technical aspects will be located in this layer. In order to make the associated standards (and thus the resulting technologies) widely acceptable, active involvement of a wide range of stakeholders in the process would be one way forward. Accordingly, especially when policies and objectives are concerned (and, to a lesser but still considerable degree, smart applications) special care should be taken to ensure broad and active stakeholder participation. To this end, contributions relating to e.g. societal, ecological, economic and ethical issue will be essential. This, in turn, will require involvement of a broad variety of (non-technical) stakeholders who are not normally represented in standards setting (including e.g. citizens, NGOs, unions, sociologists and city councils), but who can contribute the necessary expertise. How to actually achieve this in practice will be another crucial problem for which research may help finding a solution.

BRIEF CONCLUSION

Standards are crucially important, both economically and technically. This holds especially for the ICT sector and for the emerging smart systems, which simply would not function without globally accepted and implemented interoperability standards. Especially standards for smart applications will further increase the importance of standards and the underlying standardization processes, but will also require considerable interdisciplinary co-operation, thus further complicating the standards setting process.

KEY TERMS AND DEFINITIONS

Information and Communication Technology (ICT): Encompasses computer hardware and software as well as the communication networks necessary to process and transmit data.

Innovation: The implementation of a new or significantly improved product (good or service), process or new organizational method.

Intellectual Property Rights (IPR): IPR is the legal right granted with the aim to protect a creation of the intellect. These include patents, trademarks, and copyright.

Smart System: A smart system incorporates ICT functionality into ‘traditional’ technologies, thus providing them with advanced control and amenability functions.

Standard: Document, established by consensus and approved by a recognized body, that provides, for common and repeated use, rules, guidelines or characteristics for activities or their results, aimed at the achievement of the optimum degree of order in a given context.

Standardization: The process through which a standard is developed.

Standards Setting Organization: An organization that provides a platform for the development of standards.

World Trade Organization (WTO): The WTO deals with the global rules of trade between nations. Its main function is to ensure that trade flows as smoothly, predictably, and freely as possible.

ENDNOTES

- ¹ In short, according to [ISO, 2015] consensus means a general agreement, characterized by the absence of sustained opposition to substantial issues. Consensus need not imply unanimity.
- ² ITU is a United Nations agency for information and communication technology issues.
- ³ This term is used to denote both formal SDOs and private standards consortia.
- ⁴ <https://www.3gpp.org/>.
- ⁵ The World Wide Web Consortium applies the RF regime.
- ⁶ All SDOs and most consortia apply the (F)RAND regime.
- ⁷ In the following, ISO terminology will exemplarily be used.
- ⁸ See [Morales-Trujillo et al., 2015] for a detailed description of a process leading to a de-facto standard.
- ⁹ Depending on the SSO’s bylaws WG members either act in a personal capacity or represent their employer or country, respectively.

Institute for Informatics, Zagreb, Croatia

INTRODUCTION

The new technologies open the space for changing the way that business works. During the process of changing business environment the organization successfully take new position on the regional and global scene. The old tools of organizational design are not well-suited to success in new markets. Competitive advantage in new markets requires a capability to sense, shape and take new market opportunities. This means that continuous improvement of existing capabilities is not enough, but organizations should develop new capabilities that anticipate and respond to new opportunities in marketplace. Currently, digital environments push new demands on information processing in organizations. For an organization to gather these opportunities it must obtain and process current and reliable information and it asks for dynamic organization capabilities. Thus, in the process of designing organizations for dynamic capabilities there is a need for capturing information, knowledge, and experience and use it all in collective decision making. The mission of the organizational designer is to design structures that put employees in contact with their appropriate environments, and to design processes that help learning, sharing and aggregation of individual knowledge so that the collective organization can make appropriate decisions. The individual capabilities of actors must be turned into collective capabilities making an organization prepared for operating at new market environments. Opposite to traditional organization design that is centered on structural relationships actor-oriented design is centered on shared access to information and other resources as well as the protocols and infrastructures by which actors connect and collaborate. Digital organizations can apply an actor-oriented design at their origin. However, traditional organizations must be redesigned. Redesign involves changing a predominantly hierarchical system supported by legacy technologies to an actor-oriented system (Langer, 2017). Having targeted a particular area for redesign, designers and decision-makers need to address each of the components of the actor-oriented scheme (Snow, Fjeldstad & Langer, 2017).

Organization response to technological changes was dominantly gradual and enabled by information technology improvements that provide larger scope and dimensionality of organizational control and coordination. Such adaptive responses were made within existing hierarchical organization. In the context of digital technologies deployment, traditional organizations are not appropriate and require adaptation through collaboration as well as self-organization around situation awareness and knowledge commons. It is due to the fact that self-organization and collaboration, as an adaptive response, is faster and more effective than a hierarchical response. Furthermore, Rachinger (2018) states that new forms of cooperation between organizations lead to new products and service offerings as well as new forms of organization relationships with customers and employees.

DOI: 10.4018/978-1-7998-3473-1.ch068

With the huge developments in information technology and the continuing globalization, the environment for businesses changes rapidly. Changes in technology form new markets and industries and have sustainable impacts on the competitive environment. Digitalization is ubiquitous and new performances of information technology create new businesses. Furthermore, digitalization is the most powerful driver of innovation over the past few years and is acting as innovation generator making the business model concept highly relevant for research activities (Buck, 2018). One impact of digitalization on business models is business model creation, which enables new business models due to the usage of evolving digital technology. New data driven business models are exclusively build on the usage of data which is called datafication (Mai, 2016). This is caused by the reduction of marginal costs that tend to lowest level due to the high number of users. Customer experience moves towards digital integration leading to customized products improved with digital services. Hence, Engelbrecht et al. (2016) identify new categories for data-driven business models using three dimensions of data origin, target group and technology. Organizations adopting a data-driven approach have opportunities to improve their business, and outperform other organizations. Any organization planning widespread adoption of analytics and data-driven culture needs to put suitable tools to all departments. The next move is implementing data mining tools that allow users to do predictive analysis. Regardless of where advanced analytics is placed within the organization, the information technology system needs to change its focus in a way that enables easy access to data, for all the employees (Berndtsson et al., 2018).

Successful digital transformation requires a cultural shift which impacts all processes, systems, actions, and people across an organization. Companies worldwide are now highly focused on updating their business processes and adopting digital platforms that will help them serve customer needs more effectively and reliably. The recent developments that took place from 2010s, such as the mobile revolution, social media, and big data analytics, led to the digital transformation of business modeling. Anything-as-a-service models emerged were platforms with business networks and ecosystems are promoted. In the meantime, business partners can receive pervasive access to information through Internet and have multiple channels to choose from. With the help of new business modeling concepts, an organization is able to describe its business in terms of “what it does,” “what it offers” and “how the offer is made” (Ritter & Lettl, 2018). It opens the space for new organization based on an actor-oriented design in which the key element is infrastructure that relies on technologies, both operational and information technologies. These two technologies are converging with interchangeable devices, software and data connected through the same network infrastructure modeling new digital organization.

BACKGROUND

Digital technology is changing the ways of organizations activities. Organizations increasingly include digital and human agents who share means of communication, control, and coordination. Traditional organization design is centered on structural relationships. Actor-oriented design, by contrast, is centered on shared access to information and other resources as well as the protocols and infrastructures by which actors connect and collaborate. Thus, digital organizations can apply an actor-oriented design at their beginning but traditional organizations should be redesigned using actor oriented architecture. The actor-oriented architecture is composed of three elements: actors who have the capabilities and values to self-organize; commons where the actors accumulate and share resources; and protocols, processes, and infrastructures that enable multi-actor collaboration. In actor-oriented organizations, control and coordination are based on direct exchanges among the actors themselves rather than on hierarchical

planning, delegation, and integration (Snow, Fjeldstad & Langer, 2017). The data-driven organization should take digital technology change to enhance its competitive advantage. It should carefully align its business processes (supported with the proper implementation of information technology) with its environment and assure the flexibility and continuous adaptations of its core processes (Rkman, 2010). It should therefore establish which business processes are key processes and contribute to the competitive advantage creating unified infrastructure needed to support such changes. The key is infrastructure that relies on technologies, both operational and information technologies.

The increasingly prevalent role of technology in business impacted the view on information technology system strategy. Information technology strategy was seen until recent time as a functional strategy that had to be aligned to business strategy. Furthermore, information technology strategy was often presented and functioned as subordinate to business strategy. However, digitalization activates new form of business strategy that becomes digital business strategy. Hence, information technology system strategy that in past was traditional aligned to business strategy should be treated in different way because a digital organization should presume the concept of the digital business strategy. By its nature, digital business strategy is in fact an organizational strategy formulated and executed by digital resources to create differential value.

People, business, data and infrastructure are all key elements belonging to the digital transformation. Organizations use digital devices and technology for many reasons. Business benefits from technology for implement innovative processes and procedure aimed at increase profits or decrease costs. Things become smart things which include robots, autonomous vehicles, connected Internet-of-things and many other innovative technologies. Further, data represent the business assets aimed at power business and cloud represents the technological infrastructure.

Digitalization, which is defined as the exploitation of digital opportunities gain digital transformation that is then defined as the process that is used to restructure economies, institutions and society on a system level (Unruh and Kiron, 2017). Digitalization by means of combining different information technologies opens new possibilities and offers the potential to create new products and services. As a result of this new embedded usage of digital technologies, organizations can achieve further success in business activities. The digital transformation requires a methodological approach that incorporates technology and business. The digital business model should be based both on a managerial and technology language. Data-driven value propositions offer a great advantage over the traditional one. Digital data are clean, accurate, and precise but most important, provide real-time information giving business the possibility to change and adapt the value proposition to the market changing needs. Regarding operational technologies, Caylar, Noterdaeme, and Naik (2016) suggest that for the industrial sector, digitalization through the deployment of big data, analytics and the Internet-of-things brought up opportunities to increase the industry value chain. With the big data revolution many organizations are experimenting with advanced analytics as a tool to help them stay competitive. Advanced analytics go beyond traditional business intelligence solutions based on performance indicators, dashboards and the querying of data warehouses to incorporate algorithmic techniques from machine learning, artificial intelligence, natural language processing and other computer science disciplines (Rose et al., 2017). Thus, advanced analytics could be defined as the process of testing data or content using sophisticated techniques and tools to discover deeper insights, make predictions, or generate recommendations.

A central transformative force that largely influences modern organizations is digitalization that is the business effects deriving from the adoption of digital technological advancements. As a power of change, digitalization is not only seen as new applications that improve business activities, but is bringing fundamental changes to how organizations function as business entity. Hence, digitalization is pres-

ent in many different industries such as mobile applications, big data, machine-to-machine platforms, Internet-of-things, industrial Internet, and Industry 4.0. With the increasing focus on data, the business is becoming increasingly data-oriented through the increase of connected, data-collecting sensors.

The process of digital transformation can be broken down into the three separate phases including mobilization, coordination and acceleration. The first phase focuses on choosing a position based on strengths and weaknesses. The second phase involves choosing the most appropriate wave of change based on the current position. The third phase means making the most of the wave of change by entering and exiting at the right moment in time (Jansson & Andervin, 2016).

DIGITAL ORGANIZATION

An organization is a goal-directed activity system maintaining within its borders. In traditional organizations, technology, devices, and computers are controlled by human operators. With the decreasing costs of global communication and information processing, hierarchy is being replaced by new ways of organizing the digital elements that include cloud computing, big data analytics, cognitive computing, and collaboration platforms. Hence, organizing business and production activities digitally means collaboration with more entities and less dependence on hierarchy for control and coordination. This trend creates the base for new digital business strategy focused on the scope, scale, speed, and value creation according to successfully implemented technological trends such as artificial intelligence, interactive platforms, cloud computing, and the Internet-of-things.

Digital organizations strongly rely on collaboration of people and resources. According to Snow, Fjeldstad & Langerm (2017) collaboration is supported by two fundamental commons: situation awareness and knowledge. Situation awareness asks for actors a shared awareness of the resources and activities in their environment. The second common, a knowledge commons is information and data that is shared by the actors who make up the organization. Thus, the process of designing digital organization is coupled with the people, data and technology in aim to support organization's business goals.

Digital organizations operate through digital infrastructure that can be seen as complex system that goes beyond organizational and system domains, reducing information fragmentation. A digital infrastructure in its nature is an open, dynamic, complex and networked object; it contains a finite number of constituent systems that are independent and operable (Rukanova et al, 2017). Based on the new digital technology and smart devices, the digital infrastructure is evolving to new type of socio-technical information technology entity. Thus, digital infrastructure becomes a set of heterogeneous, interoperable information and operational technology systems that support business and production processes as well as technical and business actions.

The process of digital transformation makes new forms of design and works in both the processes and practices of organizations. These changes impact the conventional documented business processes and opens the need for agility and flexibility in the configuration of organizational processes during digital transformation. In the real world deployment of new technologies it is difficult to make successful control of business processes and technology infrastructures, required for flexibility, and creation of new processes. Thus, Baiyere (Baiyere et al., 2018) suggests four principles of agility during digital transformation - mindfulness, light touch routines, flexible infrastructure and ambidextrous organization. Hence, digital is not just about organizations that deliver primarily digital products and services. A digital organization is one that can operate effectively in digital age meaning that leaders in all organizations and from all sectors need a basic level of digital competence, interest and confidence. Digital organizations

are able to both understand and respond to market's rapidly changing needs, habits and expectations. Caylar, Noterdaeme & Naik (2016) state that organization that tend to be digital would treat data as a competitive advantage and must begin taking advantage of digital opportunities in order to avoid losing the value to others where a commitment to digitalization from top management is critical for success.

Digital technologies are used for learning, decision-making, and design where intelligent digital design tools are used in engineering and creative industries (Snow, Fjeldstad & Langer, 2017). Moreover, in digital organization digital technologies play a role in all aspects of operating, controlling, and coordinating the activities of organizations. It is also followed with strong collaborative decision-making and operational activities among digital and human agents. New information technologies such as artificial intelligence and machine learning embedded in machinery and tools play key role in emerging digital organizations. As a result, employees within digital organization collaborate with the technology in use, and organizational designs have to include human and digital agents. Organizing digitally means collaboration of entities without hierarchy for control and coordination. It includes partners who use digital tools for the co-creation and co-production of products and services.

Fast-moving business environments take open organization and self-organizing processes as a tool that convert individual capabilities into actionable collective intellect. Such self-organizing processes require forms and tools to design process management and execute them (Felin & Powell, 2016). It opens cooperative activities needed for digital organization. Digital technology also enables vast amounts of information to be easily compressed, preserved, and transmitted. In recent years, digital technology has disrupted one industry after another, and it is rapidly transforming how people communicate, learn, and work. Many products and services are fully or partially digital and increasingly work is being done digitally. As Langer (2017) states, the digitization of society is affecting customer needs, product and service properties and delivery mechanisms, and organization design. Thus, digitalization of organization is unavoidable task through constant adaptive learning for any organization to be competitive and agile.

Digital Business Process Management

Business process management is compilation of activities needed to create, and analyze the organization's processes that make up the core of its business. The source and fundamental order of business process management has clearly evolved over the years. During the information age the process improvement initiatives evolved by technologies such as management information systems and computer automation. The basis of structured processes led to process re-engineering using advanced technologies such as customer relationship management, enterprise resource planning and enterprise architecture, which then lead to business process management. And, as a result of more than two decades of inter-disciplinary research and excess of diverse business process management initiatives in various organizations across all industries, business process management has become a holistic management discipline. Consequently, it requires that a number of complementary elements needs to be addressed for its successful and sustainable deployment (Rosemann & Brocke, 2015).

According to Smith and Fingar (2006) the business process management is relating to the 3-tier integration and unification of data, computation and interaction. It is acceptable approach to cleaning huge data sets in new data driven organizations. Further, Anderson (2015) state that data-drivenness is about building tools, abilities, and a culture that acts on data. He also states that a data-driven organization will use the data as critical evidence to help inform and influence strategy. There will be an evidence-based culture in which data can be trusted and the analysis is highly relevant, informative, and used to determine next steps. Considering the issues with current solutions in information technology based

organizations, there is a solution with machine learning for data cleaning which consider all types of data quality issues in a holistic way and scale to large datasets.

In the process of digital business strategy development, it would be worthy to consider the development of an aligning process model that is comprised of three phases (exploratory, building, and extending) and establish organizational aligning actions that form the organization's sensing, seizing, and transforming capacities (Yeow, Soh & Hansen, 2018).

Business process management has emerged as a consolidation of disciplines that leverage process orientation to increase performance. Today, business process management has evolved into a widely deployed and comprehensively studied discipline (vom Brocke & Mendling, 2018). It also has emerged as a consolidation of disciplines that improve process orientation to increase performance. Despite the fact that business process management has disappeared as the top issue for most of organizations, process-aware management and supporting methods and technologies remains very high. Thus, the business process management is now a real opportunity.

The goal for digital organizations using business process management is to take control of their multitude processes and constantly endeavor to optimize them to create a more efficient organization better capable of delivering its end products and services. Here we can find the term maturity grid, as an assessment tool for evaluating an organization's level of progress towards a goal that could present the success of business process management deployment. Maturity grids provide an organization with a data showing how an organization is developed in regards to the criteria being assessed. They are also useful tools for leading discussions and providing management with directions for next steps. Maturity grid also represents how an organization's capabilities evolve along an established path where the basic purpose of maturity grid is to outline the stages of maturation paths. Here we could find the term hyper-collaboration. The idea here is that a process with simultaneous actions and decisions is faster and more efficient than doing them separately. In hyper-collaboration, process actors think and make decisions together simultaneously solving problems and achieving common goals.

DIGITAL TECHNOLOGY

The term frontier technologies is increasingly being used to refer to the latest generation of technologies, especially digital technologies empowered by artificial intelligence and machine learning. Further, one of the most influential advancements for an organization in the digital age is the technology that capitalizes on extremely large volumes of business data. Today, the huge volume of valuable data held in organizations is not being fully utilized. Here is the place for artificial intelligence solutions to improve data coverage and optimize the data usage.

Artificial Intelligence

At its core, artificial intelligence based system is generated by data, which can come in many different forms for many different uses. These data sets may not always seem useful and this is the scenario where artificial intelligence comes into play. One of the most universal drivers for artificial intelligence is aimed toward automation. Areas like administrative work (such as data processing and data collection) are widely seen as function where artificial intelligence technology will support workers.

Speaking of artificial intelligence, it will be strongly connected with prescriptive analytics technologies. Prescriptive analytics, which uses artificial intelligence-enabled software, will not only collect and

analyze data, making predictive statement about how that data is affecting business of entire organization, but it will also be able to define paths of business action. For many modern businesses becoming data-driven is a key priority. With more businesses looking to utilize the data they collect there is a need for new business intelligence potential of big data, artificial intelligence, and prescriptive analytics in an organization setting. This way is followed by emerged solution with augmented analytics. At the heart of this trend is the use of artificial intelligence and machine learning to augment human efforts to analyze data.

The ability of artificial intelligence based tools to quickly provide clear insights from data makes it a capable complement to Internet-of-things deployments. Further, with such tools large amounts of information can be collected, and essential patterns and insights from it can be found and automated, simplifying the process of using data. Artificial intelligence technology will be great for Internet-of-things deployment in areas such as increasing operational efficiency and enhancing risk management. Through artificial intelligence technology an organization is also able to monitor more data points and integration of artificial intelligence tools and Internet-of-things creates new and improved products and services. It opens new possibility for an organization using artificial intelligence tools with the effective process of using Internet-of-things devices to collect data from the products they are selling and generate insights about their usage. With the devices that can have embedded intelligence opens up a space for new products that couldn't have existed before. In this process, machine learning can forecast, predict and identify new forms of business processes. Thus, important outcome from the machine learning and data science process is business insights.

Internet-of-Things

Ubiquitous computing creates an environment where embedded processors, computers, sensors, and digital communication technologies are available everywhere. Ubiquitous computing will surround users with suitable information environment and a smart space that merges physical and computational infrastructures into an integrated environment. This environment will feature a large number of computing devices and sensors that will provide new functionality, offer specialized services, and increase productivity and interaction among the devices and the users.

The Internet-of-things creates a new era of networked computing where advanced applications intelligently monitor and control remote sensors, mobile devices, and smart machines. It has the ability to remove the boundary between traditional operational technology systems and information technology systems. It is also one of the most important technology trends facing business today. The Internet-of-things is actually a network of devices, appliances, vehicles and other devices that are embedded with sensors, electronics, software and connectivity enabling them to connect and exchange data. Deeper and wider knowledge about the Internet-of-things can give organizations the chance to identify operational efficiencies as well as sales and services opportunities. In many instances the Internet-of-things is driven by consumer gadgets and smart appliances that promise to transform people's lives. But the technology will not only be ubiquitous in the consumer world. It will also be deployed in the business strategies, processes and architectures of organizations across numerous industries.

Although studies show that not only product and process but also business model innovations are essential for future organization's success, both researchers and practitioners mainly focus on the technological implications of The Internet-of-things through the Industry 4.0 (Burmeister et al. 2016; Kiel et al. 2016). Additionally, studies show that business model innovators are more successful than pure product or process innovators. Business leaders and technology planners view the Internet-of-things as

a catalyst for change. Many are implementing standards-based operational control systems and replacing isolated meters, sensors, and actuators with smart, Internet based enabled devices. As a result, the Internet-of-things initiatives present a perfect opportunity to connect isolated, parallel technologies in a digital organization.

Operational Technology

Accordingly to the information technology dominance in today's organizations, proprietary operational control systems are giving way to new, open solutions based on standard information technology platforms and protocols. Further, unlike legacy operational control systems, new operational technology systems and solutions use standards-based information technology infrastructure and communications protocols to cost-effectively achieve greater flexibility, and scalability. Here we find the term operational technology as a complex set of hardware and software that detects or causes a change through the direct monitoring and control of physical devices, processes and events in the organization. In fact, operational technology means the application of computers and digital devices to monitor and control some aspect of the physical world.

We can define operational technology as technology that uses data from connected devices to monitor changes in physical processes. Operational technology is actually one application of the Internet-of-things technology. They often depend on the same server, network and operating systems that information technology systems utilize, leading to the process of information and operational technology convergence. Hence, some of the biggest changes to operational technology systems are that they are no longer stand-alone systems. In many cases, they are now connected to corporate networks to provide business information and data. And their telecommunications are increasingly being connected to the Internet in order to respond in real time to respond to system or consumer demands.

Industry 4.0

Here we find the new term in the information technology environment coping with operational technology in business processes, the edge computing. In the context of the Internet-of-things, edge refers to the computing infrastructure and devices that exist close to the sources of data. These devices typically reside away from the centralized computing system available in the cloud. Further, these computing systems are consisting more computing, storage, and analytic power to consume and act on the data at the device location. This capability will be extremely important to industrial organizations and it is opening the place for Industrial Internet-of-things known as Industry 4.0 as new, the fourth industrial revolution. It is covered by cyber-physical systems and Internet-of-things that enable smart production. Process elements can independently communicate and exchange information with each other, trigger and control the next actions, and steer the production (Pereira & Romero, 2017).

Gearing traditional industries towards the opportunities and challenges of digitalization creates the convergence of classic industrial production with information technology and new frontier technologies (Weking et al., 2018). The term Industry 4.0 also describes the digital transformation and a new manufacturing paradigm for traditional industries. With big data, advanced analytics and machine learning, industrials can reduce unplanned downtime, improve asset performance, lower cost of maintenance, and open up potential for new business models that capture value from machine data. As more computing, storing, and analytic capability is embedded into smaller devices that are installed close to the source of data edge computing will be an important tool in enabling edge processing. The important factor in

the deployment process of operational technology systems is integrated work of edge computing and cloud computing in order to fully realize the value of the massive amounts of data being generated by ubiquitous Internet connected digital devices. Using Industry 4.0-based technologies related to mobility, networking, augmented reality, and virtualization, manual procedures can be digitally transformed to help field operators execute tasks using non-electronically connected devices.

CONVERGENCE

Converging Technologies for Improving Digital Organization

Converging technologies is the process by which existing technologies merge into new forms that bring together different types of media and applications. Thus, the technology convergence capability for organizations is the ability to embed technology in devices and products leading them to business innovation, competitive differentiation across the business and increased efficiency within the organization. By convergence of information and operational technology data, devices and machines will communicate with each other without human intervention and can perform tasks that would otherwise be extremely complicated, weighty and time consuming.

The idea behind operational and information technology convergence is to integrate business process management over the whole business activities from production to market sections. In this process, the batch management system could take the initial role. The digital transformation for management activities enhance organizations to increase the usage of digital technology due to many dynamic technical and economic factors, including the use of newer complimentary technologies, such as cloud and edge computing, predictive analytics, extended reality, interoperability platforms, mobility, and artificial intelligence. As companies transform digitally, newer batch management systems will be implemented to improve processes making new possibilities for organizations to cut costs, increase performance, and drive innovation that can help them bring higher quality products to market more quickly. The trend towards real-time batch manufacturing requires greater integration between the batch management and organization's information system.

Data has become a basic organization asset that is quickly revolutionizing the business, enabling better, faster, cheaper business processes. By enabling employees at every level to use the right data at the right time, data can foster decision-making and becomes part of the organization competitive advantage. Becoming data-driven is an objective for many organizations in order to achieve digital transformation, by successfully managing data in all its forms across the whole organization processes. Hence, the organizations start to treat data as an important asset, evolve their cultures in a more data-oriented direction, and adjust their strategies to deploy data and analytics.

Thus, data-drivenness is about building tools, abilities, and, most crucially, a culture that acts on data. Culture is the key. This is a multifaceted problem that involves data quality and sharing, analyst hiring and training, communication, analytical organizational structure, metric design, decision-making processes, and more (Anderson, 2019). In the same time, a business model has many moving parts, all of which must work together in compatible way. At the heart of most digital organization ecosystems lies the unified platform. Platform is a combination of hardware and software that provides standards, interfaces, and rules that allow providers of components to add value and interact with each other. Digital technologies allow inter-operability of systems based on common standards thus unifying platforms in

entire organization. Once separated entities are now more easily integrated, creating opportunities for new business models.

With a digital setting in mind, El Sawy and Pereira (2013) included the design of a service platform and customer interface as part of business model design. This introduced questions such as whether the digital platform would be based on open or proprietary standards, and how easily the interface could be customized by users. In many industries, business and systems architects attempt to create software applications that accurately reflect their business. Unfortunately, most organizations treat information technology and operational technology as isolated technologies and project, maintain, and use each for different purposes.

Information technology systems are managed by the information technology department and support general business applications. Operational technology systems support industrial control processes or other specialized applications, such as manufacturing execution systems, energy management systems, and supervisory control and data acquisition systems. The operational technology domain favors reliability and access protection while the information technology domain favors manageability and data protection. Further, operational technology department want mission and process critical systems installed at each process place whereas information technology department prefer these systems installed in a data center. These two teams should work together in any project and deployment phase to integrate technologies across an entire organization. Smart and intelligent organization could with information and operational technologies convergence reduce the waste of energy, raw materials, time and data processing costs. This move requires a more holistic approach where two disparate team structures, different programming languages and infrastructures must be integrated. What are needed are a common strategy and architecture, increased interoperability, shared processes and a common Internet protocol. The fact that a single device or system has some Internet-of-things-enabled capabilities makes it potentially a smart device only within an interconnected technological ecosystem where it supports well-defined and purposeful business functionality.

Digital transformation or digitalization of an organization goes much further than satisfying some user demands or needs. It is no longer enough to implement silo projects that standardize business processes and role of information technology should be set changing it from an information technology supplier towards a partner within entire organization. Therefore, information technology system needs to follow operational technology deployment and adapt its services to general business plan. This is accompanied with the notion that operational technology systems are changing rapidly: and they are becoming more like information technology systems, using the same communication Internet based architecture becoming in this way more interoperable.

DISCUSSION

In the process of information and operational technology convergence there is a notion about each technology. Information technology is considered to be the whole technology stack, including the hardware, infrastructure and software applications used to transform data. An information technology system can therefore be defined as a tool that accepts data flows as an input to deliver a new data flow, but does not interfere with the physical world. Contrary, operational technology as the set of devices and processes that act in real time on physical operational systems follows its specific performances that is, up to now, generally active within its own infrastructure. Therefore, a major issue in the convergence of information and operational technology lies in adapting the organizational form to provide for common structures.

Information and operational technology convergence also requires the application of the same management framework and information technology infrastructure.

A major step in successful integration of information and operational technologies is the harmonization of their strategies. There are two aspects with regards to process harmonization. First, the common governance model will provide harmonized processes that will govern the definition of policies, workflows and structures. Second, information and operational technology convergence will also imply the harmonization of the business core processes to which the information technology and operational technology solutions will be applied. Digital organizations relied on information and operational technologies convergence have to build an agile enterprise application platform which helps a company to be proactive in carrying out its core activities. To facilitate effective integration in a modern organization, a service oriented architecture to support both macro and micro-planning is applied. In order to successfully deploy an integrated convergent information and operational technology environment, the implementation of strategies and concepts will be critical. However, their implementation will not be automatic. It will require a substantial change management effort to achieve acceptance by all subjects involved.

Information technology systems are managed by the information technology department and support general business applications. Operational technology systems support industrial control processes or other specialized applications. The operational technology domain favors reliability and access protection while the information technology domain favors manageability and data protection. Further, operational technology department want mission and process critical systems installed at each process place whereas information technology department prefer these systems installed in a data center. These two teams should work together in any project and deployment phase to integrate technologies across an entire organization. Smart and intelligent organization could with information and operational technologies convergence reduce the waste of energy, raw materials, time and data processing costs.

By unifying operational and information technology solutions around common protocols and building blocks, enterprises can connect different systems and practices to eliminate redundancies and improve business results. The implications of the integration of information and operational technology are significant. One of the issues that will occur is the cultural change required to bring these two technologies together. Additionally, this change will require a redesign of the organizational structure with a shared common purpose and strategy. New leadership is required that builds this shared strategy and direction forward. Beyond that, this convergence will require the adoption of new technical solutions, languages and skills. This will also require a significant effort to retool new processes, skills and capabilities. By unifying operational and information technology systems and practices in converged system architecture, businesses can eliminate inefficiencies and barriers to interoperability, improve automation, and accelerate innovation. Further, by adopting standards-based operational technology existing isolated operational and information technology environments, digital organization can reduce infrastructure cost and complexity and improve performance.

In most organizations, operational and information technology functions are handled by separate organizations, with distinct goals, budgets, and strategies, as well as different backgrounds and skills: This is due to the fact that operational technology systems implement and support highly specialized control systems for continuous availability for critical applications. However, information technology systems implement and support large-scale, complex, and open systems that rely on standards-based networking. To achieve a successful converged information and operational technology environment, digital organizations should coordinate programs, align plans, and share resources. By collaborating, they will be able to take advantage of integrated ability and knowledge of information and operational technology systems to successfully deploy a unified organization infrastructure.

FUTURE RESEARCH DIRECTIONS

A new area for the digital organization will presumably be merging of information and operational technologies. This direction leads to the term of convergence that becomes the imperative for future of any organizations doing business digitally. The research into information and operational technologies convergence is limited to several technological issues so there are a number of interesting directions for future research. Researching a business scenario from beginning to end where information and operational technologies convergence is actually being fully implemented is therefore an interesting direction for future research. Further, longitudinal research into the benefits of such convergence is another scope of research based on historic data that is used in advanced analytics and simulation tools predicting future states to find real ROI level of the convergence.

Since information and operational technologies convergence enables Internet-of-things utilization changing organizational management it will provide certain technological barriers that are therefore another topic to investigate. The convergence of technologies will ask for merging information technology and operational technology departments with settlement of new rules, procedures, business processes, and responsibilities that is a very complex process and is definitely a subject for future research. With new knowledge about technological opportunities and information and operational technologies convergence capabilities, the new integrated and unified ecosystem will provide opportunities for business transformation, growth and innovation. The convergence will enable and introduce new business functions improving cooperation between technology departments through digital organization enabling new ways of working and organization culture. Cultural differences between departments should be another area of future research providing a framework for successfully combining the information and operational technology staff ensuring in the same time both data availability and confidentiality.

The information and operational technologies convergence is related to the need for quantitative management reporting, assisted by big data and physical technology, artificial intelligence, cloud computing, and analytics enhancing overall business productivity. To reach all of these tasks requires network connectivity and access to both information and operational technology systems that were previously closed and are now interconnected. When they are connected they are also exposed to a huge set of risks that existing in the information technology environment. When digital organization adopts information and operational technologies convergence as its business strategy it will be exposed to new kinds of risks. Thus, the research on these newly discovered system vulnerabilities, data breach and the integrated system security is an emerged scope for the future focusing on security solutions that will effectively protects digital organizations.

There will be plenty of opportunities with information and operational technologies convergence for any digital organizations ready to implement digital integration solutions. Technology and organization development trends will remove the separation between information and operational technologies that would become the unique technology platform. It will ask for collective work of both information and operational technology sides toward the same business goals providing optimal security and productivity. This collaborative work through information and operational technologies convergence will provide hyper-collaboration scenario as a new way of teamwork in which digital organizations will process simultaneous actions and decisions in much faster and efficient way combining their skills, resources and assets in order to achieve common business goals.

CONCLUSION

Convergence of technology has been a continuous process in the industry. With recent advent in information technology, the convergence has accelerated significantly providing new concepts such as smart organizations and the Internet-of-things. Hence, information technology is developed and implemented independently of operational technology systems, thus solving different problems and employ different system architectures and communications protocols. Information technology is actually responsible for the creation, transmission, storage, and securing of data. Information technology systems were designed to connect applications and share data but operational technology systems were designed as standalone entities and were not originally intended to be connected to organizational information technology infrastructure. Operational technology is focusing on establishing and maintaining control processes with physical connections. As a result, operational technology systems were closed, independent and isolated. However, information technology and operational technology environments are inefficient and costly and new technologies can be slowed down by the resulting technological and financial limitations. Although information technology and operational technology systems coexist in many organizations they often do not work together. Such scenario is beginning to change due to new knowledge in organizational ecosystem forcing understanding of the importance of converging information and operational technology to optimize business operations and to achieve the benefits of technology implementation. With the advent of the Industrial Internet-of-things and integrating network sensors and associated software with complex physical machinery, the frontier between information and operational technologies is rapidly disappearing.

Recent developments in digital technology are making the prerequisites for these traditionally separated environments to converge. Many organizations have already begun integrating networking and digital communications into the operational technology space by deploying new Industrial Internet-of-things devices. Further, there are plenty of opportunities going forward, as more devices start to join the same network over the whole organization ecosystem. The converging information and operational technology will offer various predetermined integration solutions for plant automation, batch management and production systems with information technology applications providing new applicability for business analytics tasks. With the continuous trends in technology deployment in digital organizations, the disconnection of information and operational technology would disappear and these two technologies will become integrated entity.

To ensure this, it is important that information and operational technology systems, teams and projects jointly consider expertise and point-of-view and work together toward the same business goals of providing optimal security and productivity. By unifying information and operational technology systems and practices in a converged system architecture, digital organizations can eliminate inefficiencies and barriers to interoperability, improve automation, and accelerate innovation creating new enterprise convergence. Hence, a digital organization having a good converged technological infrastructure enriches the culture, efficiency, and relationships of its business.

In the context of the smart and ubiquitous computing devices utilization, digital organizations are reengineering their businesses by integrating activities of information and operational technology systems that manage the equipment, devices, and other components of the operational infrastructure. A huge set of shared data and tools opens new opportunities for continued collaboration and modification of the organization, business processes and investment optimization through the understanding and insight of the data. The collaboration between information technology and operational technology provides digital organizations greater capability in cost reduction of the operations, improvements in resources utilization

and lower operational risk. Integrating these environments requires digital organizations to address both technological and organizational requirements. Implementing a unified intelligent system infrastructure ensures high scalability, availability, and security, while integrated Internet-of-things gateways efficiently link information and operational technologies. In these processes of convergence deployment, effective converged infrastructure requires digital organizations to create teams that share knowledge and activities according to strategic business goals.

KEY TERMS AND DEFINITIONS

Artificial Intelligence: The simulation environment of human intelligence in computers and machines helping people and machines execute tasks and make decisions similar to a human.

Digital Organization: An organization that uses digital technology in its internal and external operations. The objective of digital organization is to transform the core of business operations and processes across entire digital organization.

Industry 4.0: The fourth industrial revolution as the cyber-physical transformation of manufacturing based on information and operational technology convergence.

Information and Operational Technology Convergence: The integration of information technology systems used for data-centric computing with operational technology systems used to monitor events, processes, and devices.

Information Technology: The infrastructure and components that enable interconnected devices, networking components, applications and systems to interact in the digital world.

Internet of Things: A system of interconnected computing devices, mechanical and digital machines, objects, or people with possibility to transfer data over a network without requiring human-to-human or human-to-computer interaction.

Operational Technology: An integrated set of hardware and software that monitors and controls how physical devices perform.

Network Organizations as a Catalyst for Innovation

INTRODUCTION

Inter-organizational networks in the economic sphere are nowadays one of the indispensable elements of the organization's functioning. Kay (1996, p. 118) describes them as "groups of companies concluding relative contracts with each other. It is also visible in Prahalad's and Ramaswamy's works (2000, p. 79). They emphasize the need to use the resources and skills of external partners, which are not connected by a connection of a proprietary or organizational nature. They stress the necessity of using so-called a deeper network that is co-created by the company and its partners, suppliers and customers. The development of network activities is possible thanks to the rapid development of computer networks and IT management infrastructure.

In its cyclically repeated report, Gartner annually identifies trends and technologies that will have a significant impact on the functioning of the organization and our daily lives. The 5 basic IT trends listed are: the democratized AI, digitalized ecosystems, do-it-yourself biohacking, transparently immersive experiences and ubiquitous infrastructure (Panetta, 2018). These technologies are based on dispersed resources, both technical and human. None of them would have a chance to grow if different, and often unrelated, resources or organizations were not used to create them. All of these modern technologies are the result of network collaboration. They are also a natural environment for its further development.

BACKGROUND

The network organization emerge as a result of the transformation of traditional structures organized in a hierarchical way into modern forms relying on the use of ICTs. These are structures that are not affected by functional and geographical constraints as much as classical organizations. Their driving force is an IT network allowing them to cross both geographic and institutional boundaries without much impediment. M. Castells (2007, p. 189) even speaks of a new type of economy (information economy) that is replacing the old-fashioned industrial approach. In the previous type of economy, the competitive advantage was generated by economies of scale, while today's new economy relies on the economics of networks which involves expanding the reach of the network, whereby the network can significantly increase its value by connecting to other networks (Castells, 2007, p.191). The establishment and operation of network organizations under the new management approach is driven by the desire to find modern and non-standard solutions, the development of knowledge and the support for innovation.

DOI: 10.4018/978-1-7998-3473-1.ch069

A network organization is defined by P. Collin (2004, p. 268) as one that functions as long as possible in isolation from the traditional structure. In order to implement specific projects and defined goals, such organizations form teams. These teams are inherently impermanent since they are dissolved after project completion and the organization looks for new projects and new resources to support their implementation. The concept of network organization is often identified with the notion of virtual organization, which is also evident in P. Collin's works, where, nonetheless, the difference is that it is the structure that distinguishes a network organization, whereas a virtual organization is unique due to its operational manner that fully relies on modern ICTs (Collin, 2004, p. 442).

Network organizations are ones that are formed as a result of a merger of different, often independent, units (Figure 1) This connection may be temporary, often confined to the completion of a defined, specific task. Collaborative relationships among organizations can be varied and may involve both material and non-material organizational resources (Zott & Amit, 2010; Niemczyk, Stańczyk-Hugiet, & Jasiński, 2012; Kisielnicki & Sobolewska, 2019). The primary goal behind the formation of such structures is to achieve synergies – faster or more efficient attainment of defined goals by pooling resources. Hence, a particular emphasis on informational connections can be seen in network structures.

Figure 1. Network organization – nodes and relations

Source: based on: (Chrisidu-Budnik, 2012, p. 52)

In this case, the nodes of the network are people or organizations joining the network. Depending on the goals pursued by the network organization, its individual members can work together, or such relationships may not occur at all. Cooperation may be of primary nature, which is a direct consequence of established cooperation. This is a relationship that results from the goals of the network organization

(Chrisidu - Budnik, 2012, 52-53). The second type of relationship - secondary, is one that results from the membership of network members to their parent organizations. These relationships are not mutually exclusive, and their existence is often a condition for the emergence of a networked organization.

Cooperative action in the form of network offers organizations the opportunity to use not only their own knowledge, skills and competences but also those of their partners. For an organization, it is a chance to build or strengthen its market position. An important role in network arrangements is played by ICT systems that support the development of new models of work, communication and collaboration. In consequence, more and more various organizational networks are being established as “extended organizations.” (Turbilewicz, 2013, p. 387). These are structures that are strongly focused on sharing, exchanging and generating knowledge, skills and competences, thereby often being the place for innovative solutions. A network is a model or metaphor that describes a system of relationships among a specified number of units. While this number can be very large in social relationships (the case of social networks), it is usually clearly defined in economic relationships. These relationships include (Easton, 1994):

- Links and interactions among units within the network, where links are long-term and interactions are short-term relationships;
- The structure and position understood as the interdependence of the elements that make up the network and, as a result, the way in which they form interrelationships;
- The process understood as a change of ties among companies as an effect of jointly implemented tasks.

NETWORK ORGANIZATION MODEL – NETWORK’S NODES AND RELATIONSHIPS

The concept of network organization is not clearly defined in the related literature. It can even be assumed that due to the unprecedented pace of changes, including changes in network organizations themselves, this definition will undergo further modifications. However, the description of a network structure in terms of the classical graph theory will form the basis for a whole range of concepts introduced to illustrate such structures. A graph is a set of vertices that can be linked by edges in such a way that each edge ends and starts at one of the vertices (Wilson, 2000, p. 19)

The vertices, in the case of a network organization, are partners and organizations that co-create it. The concept of network nodes is often used in this case (Kay, 1996, p. 118). H. Thorelli talks about the network as a minimum of two organizations operating in stable relationships (Thorelli, 1986, p. 37). Often the concept of pointing to an organization that initiated network collaboration or is of key importance in this structure (the dominant node) will also appear, as not every network relationship must be equivalent (Niemczyk 2006, p. 28). However, what is important, the variability of the environment causes that the position and its strength in the relationship may change. The organization’s position in the network structure is always dynamic and relative (Grandori & Soda, 1995, pp. 183-214). Taking into account the fact that the basic process taking place in the network is the flow of tangible and intangible resources (including knowledge), nodes that act as flow stimulators (organizations that look for sales markets) and nodes that are a flow reactor (accept orders from others) can be distinguished.

In the literature on the subject there is also the notion of so-called network capacity, which, according to research (Håkansson & Snehota 2006, p. 138), affects and can determine the position of the organization in the network. This network capacity is often determined by resources and market position, but

also by the ability to negotiate, the ability to observe the market, or the ability to interact and self-adapt to changing conditions. In such situations, it happens that the dominant node becomes not the one with the strongest resources, and the one with the ability to adapt (Andersson & Mattsson 2010, pp. 917-924). This, in turn, is largely a derivative of the ability to collect and manage knowledge resources. Network capacity is a set of processes and routine organizational behaviors aimed at exploiting the opportunities associated with embedding a company in an inter-organizational network (Mitrega, 2010, p. 101). Analyzing nodes in the inter-organizational network, their common features can be determined (Niemczyk, Stańczyk-Hugiet & Jasiński, 2012, p. 25):

- nodes create relations between each other based on the flows of resources and knowledge,
- nodes are independent of each other by capital and legally (nodes related by capital or legally occur in network organizations),
- nodes independently decide whether to enter or leave the network,
- the sum of nodes' activities brings a synergistic effect (systems of strategic, tactical and operational co-operation),
- mutual interdependence of nodes is based on the implementation of both a common and individual, subjective goal (which in the individual approach may be different),
- nodes have the ability of flexible adaptation, consisting of the ability to enter into modular interactions,
- nodes have the ability to actively learn from other participants and use synergy (the so-called team work skills),
- nodes communicate with other network members despite the high degree of heterogeneity,
- the nodes are mutually complementary (mutual provision of competencies),
- nodes can enter into a risky relationship.

INNOVATION AND THE NEED FOR CHANGES IN THE MANAGEMENT SYSTEM

The literature lists a number of factors influencing the readiness to undertake innovative activities by organizational units (Zott & Amit, 2010; Tubielewicz, 2013; Koziół-Nadolna, 2014; Kisielnicki & Sobolewska, 2019). Networking is also considered to be a particularly desirable activity, as it ensures that extra unmanaged resources (both tangible and intangible, of which human resources form important part) are guaranteed. Networking can facilitate mutual learning, which is particularly important in the innovation process. However, there is a parallel theory that does not deny the importance of network cooperation, but it speaks of the importance of close (spatially speaking) relationships and their impact on organizational creativity. It is a concept by D. Maillat and J.-C. Perrin that dates back to the early 1990s, known as "*milieu innovateur*" or "French school of proximity" (1992). This approach highlights the essence of physical space as a condition that is essential for initiating any relationship between project members. This implies that, in line with the approach of the school of proximity, innovation requires a variety of cooperative relationships, but this cooperation should not be remote and should be implemented as closely as possible in the physical sense of the word, so that interactions between participants can take place. Organizational proximity must not, however, be reduced to a geographical dimension, as is recalled by B. Pecqueur and J.-B. Zimmermann (2004). They emphasize that proximity is made up of a number of factors, such as historical or social determinants. The French school of proximity points to three basic types of proximity, which are (Pachura, 2015, pp. 54-55):

- Geographic proximity, understood as the physical distance between organizations in a given territory;
- Organizational proximity, represented by principles and formal rules of cooperation between companies;
- Institutional proximity, taken to be a common sphere of organizational behavior, including informal behavior based in many cases on trust.

At present, two types of businesses can be distinguished in terms of innovation. The first group is faithful to traditions and relies on proven methods and means, while the other is a company striving for success by introducing innovations and novel technologies to the market. The first group is focused on maintaining good relationships with regular customers and offering them proven products or services. This activity is to focus attention on the interior of the organization and to treat customers as passive consumers (Prahalad & Ramaswamy, 2005, p. 121). The actions are centered around the exchange of products between the company and the customers. Companies that use innovation in their activities are mainly geared toward the development of the organization, taking into account the dynamically changing environment they operate in. This way of running a business is reduced to developing new technologies, gaining new clients and conquering new markets. It is also important to meet customer expectations that change along with the progress of their environment. Innovation management is a highly necessary activity in modern times marked by rapid technological advancements and constant striving for change.

Factors determining innovative undertakings are (Trzepizur, 2016, pp. 55-56):

- Level of satisfaction of the needs of both individual and business customers.
- Supply structure transformations, taking advantage of the market gap.
- Possession of human and material resources, or lack thereof.
- Competition among companies - it is much more difficult to implement a new product with a large number of competitors.
- Market feel, i.e. knowledge of customer needs and the ability to estimate whether a product or service will be able to attract buyers.
- Business size - large companies are more likely to implement a new product, among other factors because of their greater financial resources and properly trained staff.
- Readiness to assume risks associated with the launch of an innovative product or service. This is due to the fact one can never be 100% sure if the novelty will prove successful and attract customers.

These factors are also evident in Figure 1, where they are elements of innovation, as represented by S. Dutta, B. Lanvin and S. Wunsch-Vincent (2017, p.11) whose view of innovation is more universal. While the above-mentioned factors were microeconomic, they were strictly dependent on the organization itself (the determinants of size or risk-taking were analyzed), whereas the second approach is more global. Economic factors influencing innovation are: institutions, human and financial resources, and infrastructure. Under the global economy, it is possible to map the factors in a transnational context that exceeds the boundaries of one country or region. It remains clear, however, that regardless of the scope of innovation and its outreach, the ultimate product is knowledge, as highlighted in Figure 2 as well.

Undoubtedly, regardless of the scope of innovation and its scope, the product that arises is knowledge, which is also indicated in Figure 2. The fact of co-creating knowledge resources is also one of the key factors in the formation of network organizations. The importance of the fact of building knowledge as

Figure 2. Innovation's inputs and outputs

Source: based on: (Dutta, Lanvin & Wunsch-Vincent, 2017, p. 11)

an additional product of networking cooperation was emphasized in numerous publications. V. Pronskikh and O. Sobolewska (2018) analyze network cooperation in international scientific projects and point out that cooperation between teams has a positive effect on the quality of knowledge created as a result of scientific projects. This factor is crucial for entities from the field of science. The quality of knowledge is critical for further development prospects and for the strategic position of every organization (Chuang, 2004; Andreeva & Kianto, 2012; Myers, 2015) and it is also truth in case of a scientific unit. The quality of knowledge created in scientific units manifests itself not only in the number and the quality of publications but also through patents and implementations. All these activities influence the position of a unit as a centre of expertise (in case of universities) and as a cooperation partner (on the part of other organisational units of a scientific nature or of a business nature). It is an extremely important element of building the market position of an organisation and then strengthening its competitive advantages. At the same time, the complexity of scientific projects, limited access to tangible and intangible resources makes it necessary to create partnerships and cooperate to achieve scientific goals. Coopetition is a new phenomenon in the history of science development. The situation when rival scientific units start cooperating happens often in this market branch.

A company that intends introduce innovations needs to perform a number of activities in order to make the first use of new technical, technological and organizational solutions. These processes are represented by two types of linear models: *technology push model* and *market pull model*. The difference between them concerns identification of the source of innovation. In the push model, fundamental research becomes the cause of innovation, and further use leads to the emergence of a new product or solution. The customer is treated as a passive user who benefits from an innovation but is not expected to cooperate in creating or developing an innovative product. The second model is an innovation that has been perceived

as a market need (P. Drucker, who mentions the importance of environmental and market observation in the novelty process, wrote about this type of innovation). In this case, the inspiration and immediate cause for the work on the new solution are customer expectations that remain unsatisfied. The recipient and the existing market gap are the driving force behind the commencement of basic research. This is referred to as a demand model, given that it is the unsatisfied demand that inspires an innovative action undertaken by the organization. The interaction of the supply and demand side in innovation is being increasingly discussed these days, and many examples of implemented and commercialized solutions show that the two sides of the classical market (demand and supply) are elements that, in the process of introducing innovation, should complement each other. The impact on innovation on the part of its potential customers is present in digital economy, a phenomenon that is more and more commonplace. This state of affairs results, to a great extent, from the ever stronger network-based cooperation between market participants.

The literature distinguishes two key approaches to the innovation process - closed and open (Chesbrough, 2003; Koziół-Nadolna, 2013; Kisielnicki & Sobolewska, 2019). The closed model is based on own resources and protection from competition. It refers to tradition and the classical trend in the sciences of organization and management. It is based on the assumption that a company is self-sufficient and that all required resources can be acquired independently, without the need for other organizational units to be involved. Limited to internal resources only, this process demands from organizations to be prepared to spend a considerable amount of both physical and financial resources as well as the need to update their knowledge, including through research and development. This is an important barrier that is particularly evident in the automotive industry, which P. Drucker described as *“the industry of industries”* (Drucker, 1946, p. 149) The sector in question leaves practically no room for small organizations and its participants are companies with strong market positions and well-known brands. These are the businesses that regularly decide to take joint action even if the partner is an active competitor. The reason for such atypical behavior is the limited access to resources, including the knowledge base, as well as the enormous costs associated with the development of further innovative solutions. In this case, there is the possibility of sharing both costs and risks between partners. Closed innovation appears to be a very convincing solution, but in a constantly changing world, fewer and fewer companies can afford to implement this strategy, precisely because of the constraints in their resources and the access to possible desirable means of production. Another factor that further hampers the choice of closed innovation is time. Even well-established organizations that do not normally struggle with access to all sorts of resources are forced by today's market to innovate as quickly as possible. Time may be another strong constraint for choosing a closed innovation strategy. The basic assumptions of closed innovation are (Koziół-Nadolna, 2014, p. 297):

- Employ properly trained staff, smart people and experienced professionals.
- Motivate employees to come up with and develop new ideas.
- If pursued, unique ideas offer a chance to become a pioneer in a given market.
- Being the first to do something in a given market in most cases is identified with a win.
- The right amount of innovation, efficient implementation and being first in the market can contribute to market leadership.
- Controlling intellectual property to prevent employees from using the innovation to the company's disadvantage later on.

The closed innovation model relies on the use of own resources. On the other end of the spectrum, one will want to manage innovation based on an open system. In today's world, most innovations are related to interactions between individuals, organizations and the environment in which they operate. This assumes, mainly, the sharing of ideas and the acquisition of good solutions from other companies. There are also ideas that are not pursued by the organizations they originate in. In such cases, it is in many respects beneficial to sell a license for such idea to another company, which at the same time contributes to additional economic benefits for the author (Kozioł-Nadolna, 2014, p. 298)

The open innovation model, mentioned in the earlier section of this chapter, is based on the assumption that in today's market environment, relying solely on the resources held by the organization no longer suffices to introduce actual innovations. Coming up with innovative solutions forces organizations to use a wider pool of resources, often those that do not directly belong to the organization. The traditional (closed) approach was based on the premise that one of the key tasks of the organization was to protect its intellectual property. Organizations that are interested in developing innovative solutions, based on the assumption of the closed model, benefit from external sources, but this is primarily reduced to market observation and the acquisition of patents, licenses or copyright to specific solutions. In the open model, meanwhile, an organization – in addition out using internal sources of knowledge - is open to partnership (Fig. 3). The list of partners for further cooperation can be very extensive and may include organizations (sometimes direct competitors) or scientific and research units.

Figure 3. Closed and Open Innovation Model

Source: (Chesbrough, 2003, p. 36)

Table 1 lists the reasons why organizations are increasingly shifting from the closed to open model in the innovation sphere. This requires the organization to update the way it thinks and perceives its surroundings, and sometimes it is strongly linked with the need to introduce a new organizational culture that differs from the current one. As pointed out by various authors – among them A. Osterwalder and Y. Pigneur (2012) whatever the case, it must be a culture founded on a solid business model that will serve as a canvas for further activity. This model will guide developments and account for change management, which has become a determinant of modern economics.

Table 1. Closed innovation vs Open innovation

Closed innovation	Open innovation
The smart people in our field work for us	Not all smart people work for us. We need to work with smart people inside and outside the company
To profit from R&D, we must discover it, develop it and ship it ourselves	External R&D can create significant value. Internal R&D is needed to claim some portion of that value
The company that gets innovation to market first will win	Building a better business model is more important than getting to market first
If we create the most and the best ideas in the industry, we will win	If we make the best use of internal and external ideas, we will win
We should control our IP, so that our competitors cannot profit from it	We should profit from other's use of our IP (license-out) and we should license in other's IP whenever it advances in our business model
We will own all results from contract research with universities	We will partner with universities to create knowledge and encourage use outside our field

Źródło: (Chesbrough, 2003)

Market changes, strongly correlated with the development of information technology, have caused a gradual blurring of boundaries between the organization and its environment. Increasingly, the value provided by the company is co-created as a result of dialogue between the organization and its "stakeholders", as noted by C.K. Prahalad and V. Ramaswamy (2005, pp. 2-5). A value co-creation model that fits perfectly into the reality of today's organization stems from interaction with the recipient of the product or service. Customers today are not just passive recipients of the finished product, but rather their co-creators (Rossi, 2011, p. 48). The shift that is taking place within organizations towards interaction and co-creation of values, as well as the emphasis on the importance of the customer and other stakeholders in this process, is shown in Table 2.

Table 2. Migrating to co-creation experiences

	Traditional exchange	Co-creation experiences
Goal of interaction	Extraction of economic value	Co-creation of value through compelling co-creation experiences, as well as extraction of economic value
Locus of interaction	Once at the end of the value chain	Repeatedly, anywhere and any time in the system
Company-customer relationship	Transaction based	Set of interactions and transaction focused on a series of co-creation experiences
View of choice	Variety of products and services, features and functionalities, product performance, and operating procedures	Co-creation experience based on interactions across multiple channels, options, transactions, and the price-experience relationship
Pattern of interaction between firm and customer	Passive, firm-initiated, one-in-one	Active, initiated by either firm or customer, one-on-one or one-to-many
Focus of quality	Quality of internal processes and what companies have to offer	Quality of customer-company interactions and co-creation experiences

Źródło: (Prahalad, Ramaswamy, 2004, p. 8)

At this point it is important to note that cooperation aimed at developing innovative solutions, services or products, can take very different forms and cover a wide range of individuals. Such interaction

can occur among active competitors, companies of similar structure operating within the same market sector – in which case one can speak of relations of cooperation. They may also be activities that are undertaken by individuals from different sectors of the economy, differing in size, organization and management model, or organizations belonging to very diverse cultures

COMMUNICATION IN NETWORK ORGANIZATIONS

The communication structure can be defined as a set of elements of a given system with different relations between them. Communication structures can be analyzed and assessed against a variety of criteria. The central criterion is the number of intermediate levels. The number of levels (intermediate tiers) determines both the degree of organizational complexity and the way in which knowledge and information are transmitted and absorbed. There is a tendency to reduce the number of intermediate levels and transmit information and knowledge directly. In many organizations, however, the traditional hierarchical communication system is applied.

Contemporary communication systems are becoming increasingly network-based and relational.

The network communication system bears the following essential characteristics (Kisielnicki & Sobolewska, 2019, 101-109):

- Flexible actions undertaken in order to continuously improve the effectiveness and efficiency of the organization as a whole;
- A constant flow of information and knowledge among all those involved: employees, investors, suppliers, customers, which is connected with cooperation in different cultures and time zones within a uniform global network;

Building teams that can quickly deliver high-quality solutions based on the knowledge gained from work in network teams.

The operation of the network communication system is described later in this chapter. It concerned the implementation of MRP systems and the design and implementation of BI systems in large organizations such as banks, trading and manufacturing companies. The network communication system was well received by the project workers. It turned out to be both efficient and effective. The use of this type of communication made it possible to achieve obvious results such as increased speed of information transfer and a reduced scale of disinformation. What is the added value? This communication model enabled the application of agile methodologies during a research project.

Apart from sets of information and knowledge, communication systems also comprise networks of relations between individual elements and their aggregates. Sets of notions as aggregates are often termed concepts. Their presentation creates conceptual schemas that, as a description of a certain domain of knowledge, can serve simultaneously as a basis for inference. Such a set of information and relations is defined as ontology. Ontology is a formal representation of a user-defined knowledge domain. It is the records of sets of concepts and relations between them. Creating ontology fulfills the tasks of the users of the communication process in a formalized way (Fensel et al., 2006). Thanks to the communication system, users will obtain the needed data, information, knowledge, ideas, and strategies. Thereby, their information needs are satisfied. The analyzed part of the communication system also includes a set of concepts, techniques and notations aimed at projecting the semantics of data, or their meaning in the outside world. The literature uses different types of notations to present information, knowledge and

their aggregates in accordance with the facts (Dumas, La Rosa, Mendling & Reijers, 2013; Karagiannis, Mayer, & Mylopoulos, 2016).

The establishment of network organizations is aided by the emergence and development of mobile technologies. It is their development that contributes to the enhanced computing power of mobile devices, increased data throughput, and users gaining access to databases and knowledge whenever and wherever they need them. Mobile technologies contribute substantially to the changes in both business and society. They have led to the formulation of new rules and patterns of communication behavior. In their works, researchers clearly pointed to the immense potential of wireless solutions for the development of communication systems (Wan, Zhuohua, Keliang & Rongshuang, 2013). Even the most complex management structures can work in this way. The intensive advancement of mobile technologies in recent years has enabled the improvement of communication processes. This has been achieved through: deployment of mobile infrastructure, smartphones, and accelerated data transmission processes. With the rapid development of mobile technologies, it will soon be possible to talk about organizations whose employees have access to the data they need, regardless of place and time. As a result, mobile technologies allow for the minimization of constraints ensuing from the distance between the sender and the receiver. These changes are aimed at supporting the management of network organizations. The contemporary communication model within a computer network provides all hosts with the same authorizations. This is interchangeability depending on the specific client-server architecture.

As argued by M. Castells, mobile solutions result in the emergence of a new power theory based on the management of communications networks in the information era. Hence, we can recognize that hierarchical structures typical of traditional organizations are gradually making room for network structures. Network organizations use BI systems, in particular Business Activity Monitoring (BAM)

The analysis of the research evaluating successes and failures of IT projects was performed on the basis of the ISBSG database (Kisielnicki & Sobolewska, 2019, 105). The database contains historical data on completed IT initiatives from a number of public and private institutions operating in various industries and administrations. These initiatives concerned both development of new and modification of existing software. The analysis shows that most IT projects exceed the pre-defined cost and time. Many publications offer a more detailed examination indicating the reasons for IT project failures list the following reasons for failures: lack of communication within the team and with stakeholders, unrealistic budget and schedule, complexity and a prototypic nature of IT systems, lack of sufficient resources or team qualifications.

The research focused on comparing two most popular communication systems used in project teams: traditional (hierarchical) and network. The research on communication systems in project teams was done for projects carried out in different years (1996–2015). The investigation covered 28 management systems for R&D projects concerning the design or implementation of IT systems. The author participated personally in 18 projects as a performer of tasks or a project manager. The data for research on other projects were obtained from documentation and interviews with project participants. Author's involvement in those projects concerned supervision over their implementation. Difficulties in conducting the research were caused by the practical impossibility to compare the effects produced by two teams using different communication systems, due to the unique nature of the analyzed situations (which is a rule in research projects). Such an experiment would require identically qualified teams carrying out the same project, hence the quantitative results are based only on expert estimates.

This set of projects provides a picture of a very broad research spectrum. The investigation covered both business (20 projects) and administrative (8 projects) organizations. Although most projects (19) were successful, they had encountered many threats in the course of implementation. The success was

assumed to be a situation where the planned project scope, implementation time and costs had not increased by more than 10% in the previous two years.

Teams of 20–60 people took part in the implementation of each project. These were both designers and cooperating specialists in various industries. Such a minimal size of the implementing team was chosen because the survey was focused on teams where implementation required cooperation of various teams. The research questions were:

- What is the effectiveness of basic communication systems in project teams (do the team members feel that they received full information and knowledge about the performed tasks from other team members)?
- What rules should be applied to manage a project team so as to ensure the best flow of information and knowledge in achieving the set objectives?
- What communication system can be recommended for the implementation of R&D projects?

The effectiveness of a communication system is understood as the degree to which the project objectives have been attained, i.e. the success as specified above. The analysis covered: documents (conceptual design and documentation of project implementation including: costs, times, scopes), special questionnaires filled in by both selected managers and designers, reports on the implementing team's discussions (in which I participated) about the causes of failures or difficulties in project implementation.

Discussions were the primary research method, supplemented by the analysis of documents and questionnaires. Documents and questionnaires showed that there were problems to be solved. Discussions about changes in the management system provided recommendations on what should be done to address these issues. Experts were very often involved in the discussion on the causes of threats. They were outsiders including specialists from cooperating teams as well as users. Any major deviation from the assumed standard (plan, schedule) was debated and considered. The analysis of documents and questionnaires verified the answer to the question of whether the decisions taken had been effective. One of the basic questions asked after project completion was: Would you like to work on the next project in the same team?

In order to enhance the analysis of the communication system, the examination occasionally covered the time within which the information given to a particular person would reach all team members. In that case, the information was transmitted as an e-mail, and the time when the message would be read was analyzed. The frequency of using a database or the frequency of sending and receiving e-mails was also investigated. The ancillary question concerned the degree of understanding and usefulness of information to the recipient. The combination of the speed of information transmission, information comprehension, usefulness and appropriate use has a decisive influence on project success understood as its implementation within the planned time span, scope and costs.

The factors that disturb communication processes in project implementation can be divided into the following groups:

- Caused by external factors: delay in the delivery of technical and financial resources, inadequate documentation provided by the user, change of legislation, change in the management system of the organization for which the project is carried out, random factor, and a team member's incapacity for work (illness);
- Resulting from internal factors such as: poor communication, lack of knowledge and experience in project implementation, conflicts between team members, errors in project management.

All the factors listed as internal are very strongly linked with the communication system. The research results formed the basis for improving the existing information transmission system. Communication systems were also analyzed against the following criteria:

- Deviations from planned costs, time, adopted parameters;
- Failure to spot threats in time;
- Conflicts during task performance;
- Lack of cooperation and failure to share knowledge with partners;
- Willingness to work on the next project in the same team.

The examination of those communication systems revealed that:

- Out of 18 network communication systems, 15 projects had been successful (i.e. over 80%) according to the previously adopted criterion;
- Out of 10 traditional communication systems, 5 projects had been successful (i.e. 50%).

Certainly, not only communication systems are responsible for success. However, the answer to the previously mentioned question: “Would you like to work again in the same team?” was symptomatic. The following responses were given in this respect:

- Traditional – hierarchical communication system: positive responses: 60–70% of managers and about 30% of designers.
- Network communication system: positive responses: 70–80% of those surveyed (it was impossible to make a precise differentiation between managers and designers for this system).

The number and gravity of conflicts were much lower in teams working in network communication systems than in hierarchical systems. The analysis of the results showed that data transmission time was about 30% shorter in network systems than in hierarchical ones.

The research on the functioning and effectiveness of communication systems make it possible to argue that the network system has an advantage over the traditional (hierarchical) one, notably as regards the following elements:

- Monitoring of implementation. Risks to implementation and deviations from planned costs, time, adopted parameters of IT systems were spotted earlier than in hierarchical systems, hence intervention decisions could be made in good time. Also, almost all staff working in network systems felt responsible for the project;
- Cooperation and knowledge transfer in task performance. There was good cooperation between co-workers in task performance and transfer of information and knowledge to their partners. No artificial barriers existed such as leaders and employees. Generally, each worker is a leader and a performer of tasks, depending on the situation;
- Problem solving. Conflicts in task implementation were much less severe than in hierarchical systems, and if they arose, they were quickly resolved within the team.

The communication system used in a network team requires a number of conditions to be met. The level of qualifications of individual employees and their willingness to work together are most important.

Such a system is difficult for individualists and people wishing to make an administrative career. In the recommended system, the career path is directly associated with professional development. Nonetheless, it should be realized that this is a system where projects are difficult to manage. The leader of the entire project bears a great responsibility, being in charge of team selection and organization and creation of an appropriate climate. Compared to the hierarchical system, the project leader should give up many managerial powers and delegate them to the implementing teams. Yet, the leader's responsibility for project implementation does not change. Therefore, many project managers, even realizing its limitations, prefer the hierarchical system as allowing for easier control of the work done by their subordinates and strengthening their formal authority.

It is quite difficult to provide unequivocal answers to the questions:

- Which of the analyzed communication systems is more effective under all circumstances of research project implementation?
- What is the economic efficiency of replacing a hierarchical communication system with a network one?

Effectiveness and efficiency depend on manifold factors. The research found that about 20% of the surveyed employees in various business areas were concerned about network communication systems. The respondents believed that such communication systems did not ensure adequate security of transmitted information. For that reason, I would like to conclude by noting that it is not only the communication system that determines the working efficiency of the project team. It is also very important to select project team members and decide on the incentive system for those implementing the project.

CONCLUSION

Managing contemporary organizations is a multi-faceted issue. This is no longer just a search for excellence by optimizing the processes carried out within the organization. While the efficiency and effectiveness of the organization process is invariably a desirable feature, the management of the human factor and its potential is at the forefront of the foreground. Human capital, initially in theories on organization and management, was treated as another, quite expensive resource at the disposal of the enterprise. Nowadays, in the conditions of a knowledge-based economy, human capital is gaining more and more importance not only at the microeconomic but also at the macroeconomic level. Man is no longer just a productive factor that affects the implementation of processes in the organization, their excellence, but becomes a potential that plays a role in a much wider scope than that set by the organization's boundary. Knowledge is the basic resource not only of a single organization but of whole economies. It is the foundation that allows the creation of innovations that are so awaited and desired in the modern world.

Contemporary innovation also changes its shape. This is no longer a closed-end innovation, created within the boundaries of a research laboratory or in the research and development department of a company. Innovations are more and more often open in nature. They are a response to expectations formulated by the recipients. This requires constant communication and exchange of opinions between the organization and its surroundings. One of the elements of this environment are customers who formulate their expectations and needs. They are an important element, but not the only one.

FUTURE RESEARCH DIRECTIONS

Modern organizations conduct an uninterrupted dialogue not only with clients, but also with partners, with competitors, with scientific entities or with administration. It is not a closed list, because in conditions of an increasingly networked world - everyone is invited to the conversation and exchange of opinions. And every opinion is valuable, because it can be an inspiration for further actions, for creating innovations

KEY TERMS AND DEFINITIONS

Communication Structure: In an organization is a set of elements of a given system with various types of relationships established between them – relationships. In the case of organizations with traditional structures, it is often a consequence of its formal structure. For a network organization, it takes a more flexible form because it is the result of achieving the objectives pursued by network nodes.

Innovation: A series of activities leading to the production of new or improved products, technological processes or organizational systems.

Network Node: A component of the network. It is a person or organization undertaking a cooperation relationship within a network structure Innovation - is a series of activities leading to the production of new or improved products, technological processes, or organizational systems.

Network Organization: Organized, polycentric structures in which traditional hierarchy-based coordination has been replaced by strengthening horizontal links. These are temporary structures created to achieve specific goals.

Open Innovation: An innovation that results from the exchange of knowledge and cooperation between organizationally independent units: enterprises, universities, or public institutions. Open innovation is based on the assumption that in modern market conditions it is no longer sufficient to introduce real innovations, relying only on the resources owned by the organization. Creating innovative solutions requires organizations to use a wider pool of resources, often those that do not belong directly to the organization.

How IT–Enabled Dynamic Capabilities Add Value to the Development of Innovation Capabilities

INTRODUCTION

Many organizations face intense pressure to transform their current business model and operations toward more sustainability, and innovation-driven organization (Dao, Langella, & Carbo, 2011; Hanelt, Busse, & Kolbe, 2016; Seidel, Recker, & Vom Brocke, 2013).

Major technology trends and developments like big data analytics, robotics, Internet of Things, and the rise of artificial intelligence are making firms' ability to change and adapt its organizations' structure, architecture, and people as crucial as its competitive strategy. However, merely possessing valuable, rare, inimitable and non-substitutional (VRIN) information technology (IT) resources within this day and age, is not enough to enhance organizational benefits and to maintain a competitive edge (Eisenhardt & Martin, 2000). Organizational capabilities, rather than IT assets, resources or products, have been suggested to be a critical competitive differentiator (Strønen, Hoholm, Kværner, & Støme, 2017; Teece, Pisano, & Shuen, 1997). These capabilities represent an organization's potential to achieve specific business strategies and management objectives using focused deployment and are considered the building blocks on which organizations compete within the business ecosystem. Eisenhardt & Martin (2000) suggested that managers use these particular capabilities through integrating, building and reconfiguring internal and external competencies to achieve competitive advantage, rather than 'simply' possessing the capabilities (Eisenhardt & Martin, 2000; Strønen et al., 2017).

As the need to innovate increases in today's business environment, IT is often an important supporting factor through adapting to its environment and meeting new demands while maintaining quality and efficiency (Rowe, Besson, & Hemon, 2017; Van de Wetering, Mikalef, & Helms, 2017). Previous studies posited the term IT capabilities, in this particular context, in an attempt to measure a firm's proficiency in exploiting its IT assets. IT capabilities—firms' ability to mobilize and deploy IT-based resources in combination or co-present with other resources and capabilities in order to differentiate from competition (Bharadwaj, 2000)—, have been viewed by past literature as complex, multidimensional constructs (Kim, Shin, Kim, & Lee, 2011; Pavlou & El Sawy, 2006; Sambamurthy, Bharadwaj, & Grover, 2003). Although there is a growing body of knowledge underscoring the pivotal role IT-enabled capabilities in the process of enhancing an organization's competitive or financial performance gains (Kim et al., 2011; Mikalef, Pateli, & van de Wetering, 2016), there is considerably less scholarship about leveraging IT capabilities and obtaining innovation, and maintain a competitive edge in the business ecosystem through the development of IT-enabled dynamic capabilities (ITDCs) (Agarwal & Selen, 2009; Mikalef et al.,

DOI: 10.4018/978-1-7998-3473-1.ch070

2016; Wade & Hulland, 2004). We define ITDCs as an organization's ability to leverage its IT assets, resources, and IT competencies, in combination with other organizational resources and capabilities, in order to address rapidly changing business environments (Mikalef et al., 2016). Organizations that optimally deploy and enable their assets, resources, and organizational IT capabilities are more innovative and effective, and more promptly respond to constitutional changes in industry and market conditions than competitors (Aral & Weill, 2007). Hence, there is a clear call for scholars to investigate and unfold the mechanisms on how IT-enabled innovation is achieved, what the antecedent and conditioning role is of IT flexibility and ITDCs capabilities, and under which market conditions innovation can be achieved (El Sawy & Pavlou, 2008; Mikalef & Pateli, 2017; Van de Wetering, Mikalef, & Helms, 2017).

This chapter aims to investigate whether or not IT flexibility facilitates the formation of ITDCs, as well as if the development of ITDCs results in any significant innovation gains. Also, we want to explore how environmental complexity shapes the effects of ITDCs in this nomological path. We argue that ITDCs reflect a firm's capacity to utilize its flexible IT infrastructure to support evolutionary fitness with the external environment (Helfat & Peteraf, 2009). In sum, we develop a conceptual model and empirically validate this model at 138 Dutch firms. Hence, in this article, we address three research questions:

“(I) To what extent does IT flexibility influence the formation of ITDCs, (II) what is the influence of ITDCs on a firm's innovation capability, and finally (III) what is the conditioning effect of environmental complexity on the above relationships?”

We structured this chapter as follows. In the next section, we outline the theoretical background and propose our research model. Next, we present that methods section, including the data collection and analyses procedures. Then, we present the outcomes of this research and discuss the results. This chapter ends with the limitations of our work, avenues for future research, and conclusions.

BACKGROUND

Resource-Based and Dynamic Capabilities View of the Firm

We ground this current work on the resource-based view of the firm (RBV), as well as the widely acknowledged dynamic capabilities view (DCV). The RBV provides a solid foundation upon which firms can identify and evaluate all relevant resources (including IT assets, infrastructure, resources, and capabilities) toward their importance and deploy them to achieve and sustain competitive advantage (Barney, 2001; Van de Wetering, Versendaal, & Walraven, 2018).

Notwithstanding the theories' pivotal role in the literature, it does not explicitly address and define how they collectively should be leveraged to derive business value. The DCV addressed these particular shortcomings as a means for firms to evolve in changing environments and maintain a competitive edge (Schilke, 2014). The DCV has been one of the most influential theories and perspectives in the study of strategic management and information systems (IS) and attempts to explain—by extending the RBV—the processes through which a firm evolves in changing environments and maintains a competitive edge (Teece et al., 1997). Due to conditions of high environmental uncertainty, market volatility, and frequent change, scholars have raised questions regarding the rate to which traditional operational and existing 'resource-based' capabilities erode and cease to provide competitive gains (Drnevich & Kriauciunas, 2011). In the context of IS literature, previous investigations examined how IS/IT and architectural assets

and resources infused in organizational capabilities can help firms renew or reconfigure their existing mode of operating (Mikalef & Pateli, 2017; Pavlou & El Sawy, 2006; Van de Wetering, 2019) and which IT investments are deemed necessary to derive sustained competitive value (Kohli & Grover, 2008).

Following the tenets of the DCV, previous scholarship argued that it is more relevant to identify the organizational and dynamic capabilities that should be targeted by IT, rather than the aggregation of IT capabilities (IT resources and IT competencies). If an organization can combine its IT resources and competencies with other organizational resources and capabilities to respond to changes in the business environment, they possess the so-called ITDCs (Mikalef et al., 2016).

IT Flexibility

The configuration of all IT interlinked assets, systems, and components, network and communication facilities, and applications within the organization is called the IT infrastructure (Kim et al., 2011). IT flexibility refers to a shareable and reusable architecture, enabling IT resources to develop and support system components quickly, allowing the organization to be innovative and react to new market opportunities as business conditions change (Kim et al., 2011; Tallon & Pinsonneault, 2011) and has emerged as a *de facto* standard (Wilkinson, 2006) for the development of the organization's IT infrastructure. The extant literature unfolded the value of IT flexibility as an enabler of digital business strategies (Overby, Bharadwaj, & Sambamurthy, 2006; Sambamurthy et al., 2003) and as a critical component to adapt IT to changing circumstances (Bharadwaj, 2000; Ray, Muhanna, & Barney, 2005).

Synthesis from past studies shows some key qualities can be defined concerning IT infrastructure flexibility. These are modularity (i.e., loose coupling), standardization, and transparency and scalability (Byrd & Turner, 2000; Duncan, 1995; Tafti, Mithas, & Krishnan, 2013). In particular, the collective and complementary effect of these qualities enables organizations to develop ITDCs that are essential to cope with changing conditions (Mikalef et al., 2016), facilitate IT-based competitive actions (Overby et al., 2006) and acts as a facilitator of evolutionary fitness and adaptiveness.

Based on the preceding discussion, we argue that higher levels of IT flexibility will enhance the formation of ITDCs. Hence, we define the following hypothesis:

Hypothesis 1: *IT flexibility positively affects the development of ITDCs.*

Innovation Capabilities

Organizations continuously need to renew. This renewing process involves their processes, products, and services, and sometimes even their culture and identity. Innovation is a necessary condition to meet the demands of high volatile markets (Mikalef & Pateli, 2017; Strønen et al., 2017). Innovation capabilities can be defined as organizations' ability to generate innovations. These innovations include fundamental changes to products, services, or technologies where incremental innovations are just refinements of the same. We broadly distinguish two types of capabilities within the innovation spectrum, i.e., incremental and radical. An innovative incremental capability is defined as: 'an organization's ability to generate innovations that refine and reinforce existing products and services' (Subramaniam & Youndt, 2005). Accordingly, a radical, innovative capability is the capability of an organization to generate innovations that substantially transform existing products, services, and technologies (Subramaniam & Youndt, 2005).

Breznik and Hisrich (2014) stressed the importance to understand the relationship between dynamic capabilities and innovation capabilities. The dynamic capabilities view goes beyond heterogeneous firm

resources and capabilities (Barney & Clark, 2007, p. p. 257) and stresses the importance of grounding a business strategy in strong dynamic capabilities (Teece, 2014). Only dynamic capabilities support evolutionary fitness and innovation within the turbulent business ecosystem (Teece, 2009, p. 7) which helps organizations to create value and prosper in the marketplace (Kindström, Kowalkowski, & Sandberg, 2013).

Finally, by leveraging ITDCs, organizations can gain access to previously unavailable sets of decision options which can ultimately enhance their ability to innovate and thus provide the potential for higher performance contributions (Drnevich & Kriauciunas, 2011; Eisenhardt & Martin, 2000). Hence, we expect that ITDCs will help organizations in the quest to incrementally and radically develop new processes, products, and services. Hence, we define the following:

Hypothesis 2: *ITDCs have a positive impact on the development of innovation capabilities*

Some studies argue that IT flexibility facilitates the development of innovation capabilities (Ahuja & Chan, 2014). Recent scholarship also contends that the coevolution and the complex interactions of flexible IT infrastructures and organizational capabilities are considered cornerstones of innovation (Van de Wetering, Mikalef, & Helms, 2017). Others studies claim that the impact of IT flexibility on innovation capability is indirect and that this effect is readily mediated by strategic IT alignment (Tallon & Pinsonneault, 2011; Van de Wetering, Mikalef, & Pateli, 2017). Hence, Tallon (2011) explains how IT flexibility creates digital options, which can help organizations transform and align IT with business strategy (Tallon & Pinsonneault, 2011). Apart from this, researchers have argued that IT flexibility can strengthen the sensing, responding, and reconfiguration routines that are part of ITDCs. Overall, the combined effect of ITDCs and flexibility offered by the organization's IT infrastructure is expected to enhance innovation capabilities. Hence, we define the following hypothesis:

Hypothesis 3: *ITDCs positively mediate the effect of IT flexibility on innovation capabilities*

Environmental Complexity

In today's business environment, unpredictable rapid changes and uncertainties have become 'the new normal' (Kim et al., 2011). Research has acknowledged the influential role of external environmental factors on the relationship between IT capabilities and business outcomes (Chen et al., 2014). These environmental factors are environmental hostility, dynamism, and complexity (Chen et al., 2014). Hostility defines the scarcity of resources and level of competition; dynamism denotes the unpredictability of environmental changes, and complexity concerns the diversity of the market and the heterogeneity and range of an industry and/or an organization's activities (Chen et al., 2014; Mikalef & Pateli, 2017; Wade & Hulland, 2004). Unexpected market changes can force organizations to change their business strategy, thus, sensing the need for developing new combinations of IT capabilities and resources becomes a necessity in dynamic markets (Strønen et al., 2017; Tallon & Pinsonneault, 2011; Teece et al., 1997).

Studies have acknowledged the permeation of IT in all aspects of organizations and the importance of IT assets, resources, competence, and capabilities in enabling business abilities that help firms survive, thrive (Aral & Weill, 2007; Dao et al., 2011; Kim et al., 2011), and support evolutionary fitness with the external environment (Helfat & Peteraf, 2009). Innovation capabilities are crucial for organizations to achieve congruence with this dynamic environment (Kindström et al., 2013; Teece, 2007, 2010; Van de Wetering, Mikalef, & Helms, 2017). Previous research contends that a firm's proficiency in IT capabil-

ity development and flexible IT infrastructures in highly complex environments is strongly associated with efficient operations management and competitive process capabilities (Byrd & Turner, 2000; Rai & Tang, 2010; Wade & Hulland, 2004). That is, organizations that have a sophisticated IT capability and flexible infrastructures are better equipped to sense, analyze, seize opportunities, and more likely to transform and disseminate information and business opportunities in the day-to-day operations. Thus, sensing, responding, and innovation capabilities become a necessity in uncertain environments. We, therefore, assume that the environmental complexity will be an essential catalyst for the likely effect that ITDCs have on innovation capabilities.

Based on the above rationale, we formulate the following two hypotheses:

Hypothesis 4a: *A considerable degree of environmental complexity positively moderates the effect of IT flexibility on the development of ITDCs.*

Hypothesis 4b: *A considerable degree of environmental complexity positively moderates the effect of ITDCs on the development of innovation capabilities.*

EMPIRICAL STUDY

Research Approach and Data Collection

This research follows a positivistic research philosophy. This philosophy emphasizes that new knowledge can only be acquired through the correct application of a strictly scientific method where the focus is on discovering observable and measurable facts (Saunders, Lewis, & Thornhill, 2016). The method should be designed to yield pure data and facts which are not influenced by bias or interpretations (Saunders et al., 2016). We apply quantitative research because of the highly-structured data collection techniques. Through a deductive approach, we use and analyze data to evaluate a priori defined hypotheses related to an existing theory. The developed hypotheses will be tested and confirmed or refuted, allowing further development of the theory (Saunders et al., 2016).

We approached respondents directly through our (social) networks. This method is called respondent-driven sampling. We only identified and selected respondents that have sufficient knowledge and experience to avoid uninformed and unreliable responses. Thus, the target audience was selected based on convenience sampling. We identified Chief Information Officers (CIO's), Chief Executive Officers (CEO's), Chief Technology Officers (CTO's), innovation managers, IT managers and enterprise architects to be most familiar with our study concepts. During the data collection, we kept track of which respondent from which organization completed the survey, to make sure that every organization completed the survey only once. We also ensured that different organizations from a wide range of businesses, industries of various sizes were included. Respondents were given an incentive to take part in the survey. They were offered a benchmark report to gain insights on how well their organization scores compared to others in the same industry.

The data collection phase started on the 26th of February 2018 and ended on April 9th of 2018. In total, 610 respondents from different organizations were asked to fill in the survey. Based on the final response, a total of 138 usable questionnaires could be included for the analyses, i.e., a response rate of 23% which is acceptable for these type of studies (Baruch & Holtom, 2008). The majority of responses were from the private sector 62,3%, 30,4% from the public sector and a small percentage from non-profit (4,3%), non-governmental organizations (1,4%) and other categories (1,4%). Most responses were from

large organizations with 250+ employees (71%), 50-249 employees (14%), 10-49 employees (9%), and the remaining 6% had less than 9 employees. More than half of the organizations were founded over 50 years ago.

We controlled for potential common method bias (CMB). We, thus, performed Harman's single factor test using IBM SPSS Statistics™ v25 on our main study constructs. Hence, we loaded all construct variables on to a single construct in an Exploratory Factor Analysis (EFA). Outcomes of this analysis showed that no single factor attributes to the majority of the variance. We, therefore, conclude that our sample is not affected by CMB (Podsakoff, MacKenzie, Lee, & Podsakoff, 2003).

Items and Constructs

The survey started with questions on the background information of the organization, such as size, industry, and age of the organization. All the primary constructs of our based on past empirical and validated work to increase the internal validity of the questions (Chen et al., 2014; Mikalef et al., 2016; Newkirk & Lederer, 2006). The entire survey was pre-tested by six Master students and a small panel of expert, including three managers/consultants from practice and two academics to ensure face and content validity. We evaluated all survey items on a 7-point Likert scale. We included the entire survey in Appendix A.

We included the following dimensions for IT flexibility, i.e.: (1) loose coupling, (2) standardization, (3) transparency, and (4) scalability. The following routines for ITDCs were adopted: (1) sensing, (2) learning, (3) coordinating, (4) integrating and (5) reconfiguring routines (Mikalef et al., 2016; Pavlou & El Sawy, 2011; Teece, 2007; Teece et al., 1997). Next, the measures for the two types of innovation capabilities (i.e., incremental and radical) are based on the items provided by Subramaniam and Youndt (2005). Finally, we used the construct items assessed by (Chen et al., 2014; Mikalef & Pateli, 2017; Newkirk & Lederer, 2006) to measure the degree of environmental heterogeneity, complexity.

DATA PREPARATION AND ANALYSES

We analyzed the obtained data using the software package IBM SPSS Statistics™ V25 and hence test the hypotheses. All constructs and measurement items were subjected to various assessments, including internal consistency, reliability, construct, and discriminant validity assessments. For operationalization purposes, we conceived all the model's constructs to be reflective of nature. Hence, the manifest variables are affected by the latent variables (Wetzels, Odekerken-Schröder, & Van Oppen, 2009). Hence, at the construct level, we checked internal consistency reliability using Cronbach's Alpha values and check whether they all exceeded the threshold of 0.7 (Santos, 1999). Also, we calculated the composite reliability (CR) values for each construct as this measure takes into account the loadings of the manifest variables (Hair Jr, Hult, Ringle, & Sarstedt, 2016). Typically, CR values should be between 0.60 and 0.90, as is the case in our research (see Table 1). Also, we assessed the construct-to-item loadings. We assessed the convergent validity by examining if the average variance extracted (AVE) of each construct is above the lower limit of 0.50 (Fornell & Larcker, 1981). Next, to convergent validity, we also discriminant validity through three different, but related tests (Farrell, 2010). First, we examined if the cross-loadings on other latent constructs are less than the outer loading on the associated construct. Next, we assessed the Fornell-Larcker criterion. In doing so, we investigated if the square root of the AVEs of all constructs is larger than the cross-correlation. All correlations among all constructs were below the common threshold (0.70). The outcomes of these assessments in Table 1 suggest that the constructs are valid and reliable.

Table 1. Assessment of convergent and discriminant validity of the model's constructs.

7. Coordinating	0.478	0.452	0.467	0.463	0.613	0.591	0.870					
8. Integrating	0.439	0.448	0.459	0.474	0.706	0.625	0.736	0.868				
9. Reconfiguring	0.589	0.280	0.488	0.474	0.644	0.576	0.664	0.654	0.845			
10. Incremental innovation	0.412	0.160	0.353	0.270	0.516	0.373	0.391	0.386	0.501	0.936		
11. Radical innovation	0.401	0.209	0.434	0.255	0.485	0.375	0.433	0.380	0.475	0.668	0.926	
12. Env. Complexity	0.104	0.155	0.086	0.113	0.206	0.031	0.059	0.224	0.133	0.166	0.083	0.834
Cronbach's Alpha	.89	.90	.85	.84	.86	.93	.89	.89	.86	.93	.92	.78
Composite reliability	.92	.88	.89	.93	.91	.95	.93	.93	.91	.96	.95	.87
AVE	.65	.59	.59	.76	.71	.71	.76	.76	.71	.88	.86	.70

We used principal component analyses (PCA), and the preceding Kaiser-Meyer-Olkin measure of sampling adequacy (KMO) (Kaiser, 1974) scores and Bartlett's test of sphericity tests, to assess whether or not we could reduce the multiple items per construct to a single construct measure. Hence, we subsequently used the average values of the constructs items to represent the latent constructs.

Before running the multiple regression analyses, there are some necessary assumptions to be checked that make sure this dataset is appropriate to use linear regression to give a valid output. First, we excluded seven detected outliers to prevent any adverse effect on the regression analyses. Next, we checked the data for normality using a normal P-P plot. We used scatterplots for homoscedasticity analyses. We met all the underlying assumptions. Therefore, the linear regression analyses results can be considered valid. We used a macro for SPSS called 'PROCESS' (Hayes, 2013) to run our analyses.

RESULTS

We use PROCESS to assess our research model, thereby examining the proposed complete set of hypotheses. Results of the regression model are as follows. 33% of the variance for innovation capabilities can be explained ($R^2 = .33$) through the research model. The model is significant ($p = <.05$).

The results in Table 2 support **H1** in that two organizations that differ by one degree in the flexibility of their IT infrastructure differ by 0.747 units in their indication of being effective in using IT systems to sense, integrate, coordinate, reconfigure and learn. The regression coefficient for ITDCs on innovation capabilities, $b = 0.351$, subsequently supports **H2**, i.e., two organizations having the same degree of IT flexibility but differ by one unit in their ITDCs are estimated to be relatively stronger in their perceived innovation capabilities by 0.351 units.

Table 2. Model coefficients for the mediating model

		Consequent						
		ITDCs (M)				Innovation capabilities (Y)		
Antecedent		Coeff.	SE	p		Coeff.	SE	p
Constant	i_M	0.779	0.387	<.050	i_Y	2.210	0.328	<.001
IT flexibility (X) (H1)	a	0.747	0.081	<.001	c'	0.165	0.087	.061
ITDCs (M) (H2)		-	-	-	b	0.351	0.074	<.001
		$R^2 = 0.40$				$R^2 = 0.33$		
		$F(1, 129)=85.6, p=<.001$				$F(2, 128)=31.5, p=<.001$		

Mediation Model

We used ordinary least squares path analysis to analyze the mediation effects. Hence, IT flexibility indirectly influences innovation capabilities through its effect on ITDCs. This indirect effect was calculated through the product of path a and path b (ab). The bootstrap confidence interval for this indirect using 5,000 bootstrap samples, is between 0.160 and 0.378. This confidence interval is entirely above zero. Therefore, this outcome supports the conclusion that the indirect effect is positive and, thus, provides evidence for ITDCs role as a facilitator of the effect of IT flexibility on innovation capabilities. Next, we will analyze if this effect is fully mediated or partially. The estimated direct effect (c') of IT flexibility on innovation capabilities is $c' = 0.165$, but misses statistical significance using an $\alpha = 0.05$ decision criterion, $t(2, 128)=1.894, p = 0.061$. So, this research finds no evidence of IT flexibility affecting innovation capabilities independent of the mediated effect of ITDCs. The total effect of IT flexibility on innovation capabilities is $c = 0.427$, and since c' is not statistically significant, ITDCs is marked as a complete mediator of the interaction, supporting **H3**. What this means is, that without the influence of ITDCs the flexibility of an organizations' architecture cannot affect its capability to innovate.

Moderated Mediation Model

Although the estimated difference in strength of ITDCs caused by IT flexibility is significant for $b = 0.747$ at $p = <0.001$, the regression coefficients for the direct effect of environmental complexity on ITDCs $a_2 = -0.043, p = 0.868$, as well as the interaction effect IT flexibility and environmental complexity $a_3 = .019, p = 0.728$ miss statistical significance. So, this research rejects **H4a** as it finds no evidence for the conditioning effects of environmental complexity. The absence of a direct moderation effect means no two conditional direct effects can be considered statistically different from each other. The same applies to the effect of environmental complexity on the development of innovation capabilities through ITDCs. The direct effect of environmental complexity on innovation capabilities is not significant at $b_2 = -0.124, p = 0.475$. Next, the product of ITDCs and environmental complexity also misses statistical significance at $b_3 = .036, p = 0.367$. Thus, the degree of environmental complexity does not moderate the effect of ITDCs on the development of innovation capabilities. Therefore, we also reject **H4b**; a particularity that we will discuss.

Figure 1 summarizes all the assessed relationships.

Figure 1. Estimated causal relationships of the research model. The * is used to denote a significant relationship.

DISCUSSION

This study examined if IT flexibility facilitates the formation of ITDCs, as well as if the development of ITDCs results in any significant innovation gains. An important outcome of this study is that the development of ITDCs is positively affected by the degree of IT flexibility. This outcome confirms previous findings by Mikalef et al. (Mikalef et al., 2016), although we even find an even stronger beta coefficient ($\beta = 0.75$).

Previously, Breznik and Hisrich (2014) called for empirical validation of the relationship between ITDCs and an organization's innovation capabilities. Our study finds a significant relationship between ITDCs and organization's aggregated innovation capabilities ($\beta = 0.351$). The combined impact of IT flexibility and ITDCs explain 33% of the variance in innovation capabilities. These outcomes also corroborate with previous claims that strengthening ITDCs in isolation is not sufficient to substantially enhance organizations' capability to innovate (R. Van de Wetering, P. Mikalef, & A. Pateli, 2017). Therefore, our current study extends the current practical and theoretical knowledge base that has paid little attention to organizational innovativeness, and IT-enabled business transformations in complex environments.

We would expect that the previously discussed mediation effect would be moderated by environmental complexity (Strønen et al., 2017; Tallon & Pinsonneault, 2011; Teece et al., 1997). However, we currently did not find any evidence to support that the diversity of the market fosters the value-adding effects of ITDCs. This outcome means that within our study, the effect of IT flexibility, through ITDCs on organizations' capability to innovate is not influenced by the market diversity. This rather weak conditioning effect might be attributed to a large part of the respondents that work in the public sector. Various respondents argued that environmental complexity questions were less relevant for their particular organizations (operating in the public sector and non-profit sector). Many other environmental factors can be taken into considerations.

This work has some interesting practical implications. Our study provides insights for organizations, mainly for IT and business managers, regarding the usage of IT to develop innovation capabilities. Hence,

we highlight the importance of maintaining the organization's IT infrastructure modular, scalable, and transparent, but organizations should mainly strategically invest in developing their ITDCs. Thus, if organizations want to achieve significant innovation capability gains, it is strategically imperative to develop their respective capabilities to sense, learn, coordinate, integrate, and reconfigure.

FUTURE RESEARCH DIRECTIONS

Despite its contributions, this study includes several limitations. First, we conveniently sampled our data. A potential disadvantage of this particular method is that our sample might not be representative of the full population (Heckathorn, 2002). A stratified sampling method that a priori includes various subgroups within a population remedies this. Second, we only asked a single respondent to fill in the survey. Future research could employ a matched-pair approach through which independent and dependent constructs are provided to different stakeholders within the organization. An alternative could also be to have multiple respondents per organization fill in the survey to gain a holistic view of the capabilities and environment of the organization. Third, our obtained survey data included various demographic variables (e.g., organization type, size). However, our empirical analyses did not take into account the possible differences among sub-groups of organizations. Also, comparing the strength of the relationships across the organization from different countries might well contribute to the generalizability of our findings. Finally, a more substantial sample space could then also contribute to more robust results.

CONCLUSION

To conclude, ITDCs are essential for the organization in the modern age. Our study tried to explain how organizations—that operate in turbulent environments—can differentiate to stay competitive, considering that they must evolve and reconfigure their processes to drive innovation. By considering the key antecedents and mechanisms through which innovation capabilities can foundationally be enhanced, we make valuable contributions to the literature. Our work also serves as a basis for future investigations.

KEY TERMS AND DEFINITIONS

Environmental Complexity: The heterogeneity and range of industry and/or an organization's activities.

Incremental Innovation Capability: Organizations' potential to generate innovations that refine and reinforce existing products and services.

IT Capability: Firms' ability to mobilize and deploy IT-based resources in combination or co-present with other resources and capabilities in order to differentiate from the competition.

IT Flexibility: The degree of decomposition of an organization's IT portfolio into loosely coupled subsystems that communicate through standardized interfaces.

IT-Enabled Dynamic Capabilities (ITDCs): Firm's ability to leverage its IT resources and IT competencies, in combination with other organizational resources and capabilities, to address rapidly changing business environments.

Organizational Capabilities: An organization's ability to achieve specific business strategies and management objectives using focused deployment and are considered the building blocks on which firms compete within the business ecosystem.

Radical Innovation Capability: Organizations' the capability of an organization to generate innovations that substantially transform existing products, services, and technologies.

APPENDIX: SURVEY ITEMS

Table 3.

IT flexibility			
<i>To what extent do you agree with the following statements? (1-totally disagree, 7-totally agree)</i>			
Modularity		<i>Mean</i>	<i>S.D.</i>
$\alpha = .89$	KMO = .83		
[Mod 1]	Our information systems are highly modular.	4.28	1.580
[Mod 2]	The manner in which the components of our information systems are organized and integrated allows for rapid changes.	3.97	1.691
[Mod 3]	Functionality can be quickly added to critical applications based on end-user requests	4.22	1.720
[Mod 4]	Exchanging or modifying single components does not affect our IT infrastructure.	4.42	1.699
[Mod 5]	Organizational IT infrastructure and applications are developed on the basis of minimal unnecessary interdependencies	4.33	1.581
[Mod 6]	Organizational IT infrastructure and applications are loosely coupled.	4.23	1.544
Transparency		<i>Mean</i>	<i>S.D.</i>
$\alpha = .85$	KMO = .78		
[Trns 1]	Remote users can seamlessly access centralized data and processes	5.16	1.671
[Trns 2]	Our user interfaces provide transparent access to all platforms and applications	4.44	1.776
[Trns 3]	Software applications can be easily transported and used across multiple platforms	3.99	1.814
[Trns 4]	Data of one system can be easily used in other systems.	3.97	1.771
[Trns 5]	Our firm offers multiple interfaces or entry points (e.g., web access) to external users	4.62	1.772
Standardization		<i>Mean</i>	<i>S.D.</i>
$\alpha = .90$	KMO = .76		
[Stnd 1]	We have established corporate rules and standards for hardware and operating systems to ensure platform compatibility.	5.02	1.623
[Stnd 2]	We have identified and standardized data to be shared across systems and business units.	4.53	1.576
[Stnd 3]	Our systems are developed based on specifications that enable electronic links to external parties.	4.51	1.613
[Stnd 4]	Organizational IT infrastructure are developed based on compliance guidelines.	5.30	1.448
[Stnd 5]	Organizational IT applications are developed based on compliance guidelines.	5.20	1.469
Scalability		<i>Mean</i>	<i>S.D.</i>
$\alpha = .83$	KMO = .82		
[Scal 1]	Our IT infrastructure easily compensates peaks in transaction volumes.	5.00	1.460
[Scal 2]	Our information systems are scalable.	5.05	1.457
[Scal 3]	Our IT infrastructure offers sufficient capacity in order to fulfil additional orders.	5.32	1.424
[Scal 4]	The performance of our IT infrastructure completely fulfils our business needs regardless of usage magnitude.	4.68	1.519
ITDCs			
<i>Please indicate how effective your company is in using IT systems for the following purposes: (1-Not effective at all, 7-Highly effective)</i>			
Sensing		<i>Mean</i>	<i>S.D.</i>
$\alpha = .86$	KMO = .79		
[Sns 1]	Scanning the environment and identifying new business opportunities	3.95	1.609
[Sns 2]	Reviewing our product development efforts to ensure they are in line with what the customers want.	4.46	1.635

IT flexibility			
<i>To what extent do you agree with the following statements? (1-totally disagree, 7-totally agree)</i>			
[Sns 3]	Implementing ideas for new products and improving existing products or services.	4.60	1.573
[Sns 4]	Anticipating discontinuities arising in our business domain by developing greater reactive and proactive strength	4.07	1.544
<i>Integrating</i>			
$\alpha = .89$ KMO = .79		Mean	S.D.
[Int 1]	Easily accessing data and other valuable resources in real time from business partners	4.44	1.621

Toward a Fitness Landscape Model of Firms' IT-Enabled Dynamic Capabilities

6

Open University, The Netherlands

INTRODUCTION

Scholars posit that information systems and information technology (IS/IT) are capable of revolutionizing the way firms operate, and hence drive a firm's performance under rapidly changing conditions (Agarwal & Selen, 2009; El Sawy, Malhotra, Park, & Pavlou, 2010; Kohli & Grover, 2008; R. Van de Wetering, Mikalef, & Pateli, 2017b). In understanding this particular role of IS/IT within the turbulent business ecosystem and landscape, previous studies have emphasized the importance of IS/IT in enabling organizational capabilities (Kohli & Grover, 2008). Organizational capabilities represent firms' potential to achieve specific business strategies and management objectives using focused deployment and are considered the building blocks on which firms compete within the business ecosystem (Barney, 1991). Firms that are capable of targeting and deploying IS/IT initiatives in support of these organizational capabilities are more likely to realize business value from their IT resource and IT competencies inventory (Sambamurthy, Bharadwaj, & Grover, 2003; R. Van de Wetering, Mikalef, & Pateli, 2017a). The extant literature refers to this specific capacity to effectively use IT functionalities to support IT-related activities as an IT leveraging competence (Pavlou & El Sawy, 2010).

The core principle of examining the particular value of IS/IT in enterprise processes it is embedded, i.e., IT-enabled capabilities is also highly encouraged in contemporary IS literature (Grover & Kohli, 2012; Kohli & Grover, 2008; Mikalef, Pateli, & van de Wetering, 2016). IT-enabled capabilities gained considerable as they collectively create business value and drive a firm's competitive edge (El Sawy & Pavlou, 2008; Mithas, Tafti, Bardhan, & Goh, 2012; Roberts, Galluch, Dinger, & Grover, 2012).

The capabilities we address in this current study constitute the dimensions of IT-enabled dynamic capabilities (ITDC). We define ITDCs as a firm's ability to leverage its IT resources and IT competencies, in combination with other organizational resources and capabilities, to address rapidly changing business environments (Mikalef et al., 2016). Based on the notion that firms must be able to be stable enough to continue to deliver value in their distinctive way, and agile and adaptive enough to restructure their value proposition when circumstances demand it, there is a well-documented distinction between ordinary (operational or zero-order) and these ITDCs (Drnevich & Kriauciunas, 2011; Mikalef et al., 2016; Pavlou & El Sawy, 2011; Winter, 2003). Ordinary capabilities enable a firm to make a living in the present, while ITDCs act as a continuous driver of evolution to changing business requirements (Winter, 2003). Thus, ITDCs help firms decision-makers in practice by extending, modifying, and reconfiguring existing operational capabilities into new ones that better match the environmental conditions.

There is overwhelming evidence concerning the impact of ITDCs on firm performance at an aggregate level (Mikalef & Pateli, 2017; Rai & Tang, 2010). However, there is still little consensus on how

DOI: 10.4018/978-1-7998-3473-1.ch071

specific interrelations (e.g., too many or too little epistatic links and interdependency among individual capabilities) result in the achievement toward higher levels of performance and evolutionary fitness. Moreover, the extant literature has predominantly focused on the aggregate construct level of ITDCs.

Consequently, there is no clear overview of what constitutes useful configurations of the underlying interdependencies. A better understanding of the nature and role of ITDCs may have profound implications for theory and practice. In doing so, this study builds on the science of complexity recently become a significant focus of interdisciplinary research, also within the IS field (Benbya & McKelvey, 2006; Merali, Papadopoulos, & Nadkarni, 2012; R. Van de Wetering & Bos, 2016; Rogier Van de Wetering, Mikalef, & Helms, 2017; Walraven, Van de Wetering, Helms, Versendaal, & Caniëls, 2018). This chapter adopts a prominent model for studies in theoretical biology and population genetics, i.e., the so-called NK-model (S. Kauffman & Levin, 1987; S. A. Kauffman, 1993), that evolved into a valuable model to understand the antecedents of efficient, flexible, innovative and IT-enabled firms (Celo, Nebus, & Wang, 2018; Onik, Fiel, & Gable, 2017; Vidgen & Wang, 2006; Yuan & Jiang, 2015).

This study aims to address the previously outlined limitations in the literature by drawing on complexity science while simultaneously building on the foundations of ITDC. In doing so, this current study makes four main contributions. First, this chapter positions the science of complexity and evolutionary (simulation) models as a suitable 'lens' to study the behavior of firms' ITDCs. This lens has also been advocated by recent studies (Kay, Leih, & Teece, 2018; Onik et al., 2017). Second, following Kauffman's work (S. Kauffman & Levin, 1987; S. A. Kauffman, 1993; S. A. Kauffman & Weinberger, 1989) this study designs the NK-model and stochastically generate fitness landscapes using the five ITDCs as core elements of the model, and 'K' complex interactions between those five, i.e., the interdependency (epistasis). Third, firms' effort is simulated to adaptively explore and walk through a generated fitness landscape of possible strategies of interrelated ITDCs to change and move toward higher levels of fitness of ITDCs. Finally, this chapter identifies which degree of epistasis on average leads to optimal fitness values and hence firms' competitive performance.

Outcomes of our work provide new empirical support for possible business strategies that can be employed considering a firm's current status and interdependency among its ITDCs¹. To our knowledge, no scholarship is available that identifies these specific interactions among the different ITDCs and uses the NK-model to do so.

The remainder of this chapter is structured as follows. First, this chapter reviews the fitness landscapes theory and Kauffman's NK-model. Next, our methods section is outlined including the simulation model parameters, and the outcomes follow this section. This chapter ends with a discussion, including inherent limitations of this study as well as future research opportunities, and concluding remarks.

THEORETICAL BACKGROUND

Complexity science addresses the summon of adopting a dynamic methodological approach, in which scholars and practitioners are equipped with adequate assessment tools and mechanisms for examining the processes when IT and associated capabilities add value (Rogier Van de Wetering et al., 2017). This paper draws upon foundational and empirical work and presents, extends and integrates a complex adaptive systems perspective and applies this to the firm's ITDCs.

The NK model from population genetics and theoretical biology (S. Kauffman & Levin, 1987; S. A. Kauffman, 1993; S. A. Kauffman & Weinberger, 1989) has become a particularly popular reference model for studying strategy, organizational, and innovation problems and challenges through the use

of fitness landscapes (Frenken, 2006; Ganco & Agarwal, 2009; Daniel A Levinthal, 1997; McKelvey, 1999; Rivkin & Siggelkow, 2007). The model (originally) simulates an organism's adaptation and self-evolvment processes in complex and turbulent environments. Recent literature advocated the use of the NK-model to simulate and examine, e.g., organizational structure, change, and adaption (Daniel A Levinthal, 1997; Daniel A. Levinthal & Warglien, 1999; McKelvey, 1999), system and technology architecture (Frenken, 2006), business strategies (McCarthy, 2004) and enterprise intellectual capital (Fan & Lee, 2012) under the complexity science 'lens.'

The NK-model consists of N elements (in our case ITDCs), and K represents the richness of epistatic linkages (term used to describe interacting genes) among those elements. Alternatively, as Kauffman (S. A. Kauffman & Johnsen, 1991) defines it: "*K corresponds to the number of other genes, or traits, which have a bearing on the fitness contribution of each gene or trait.*" This richness of epistatic interactions among sites makes it possible for, e.g., a population to evolve toward different combinations of alleles depending on its initial genetic composition (S. A. Kauffman & Weinberger, 1989). The possible alleles of a particular element of a system can formally be described. Each string x is described by $x_1x_2x_3\dots x_n$. These strings are part of a solution or possibility set X , so that for two allelic values, or a two-allele additive haploid genetic model, as Kauffman (S. A. Kauffman & Johnsen, 1991) favors it we have:

$$x = x_1x_2x_3\dots x_N \in X; x_i \in \{0,1\}$$

The N -dimensional possibility space X is called the design space of a system. It, therefore, includes all possible combinations of the alleles of the individual system elements (Frenken, 2001). If we, thus, assume that each element within a system has two possible values, the binary strings with $N = 3$ can take the form of 000, 010, 101.....111. These strings are part of the entire possibility space which we formalize as $X = 2^N$.

In general, the degree of interaction and interconnectedness between those N elements, i.e., K , ranges from $K = 0$ (the least complex) to $K = N - 1$ (having the most complex architecture), and influences the ruggedness of a fitness landscape. With $K = 0$ the system's elements are independent concerning the fitness of all other elements. When a system is fully interconnected, each element is connected to all other elements. With low levels of epistatic linkages among elements (e.g., $K = 0$) the fitness landscape tends to be smooth with a single performance or fitness peak.

The fitness contribution of each element or trait depends upon itself and thus epistatically on K other traits (Altenberg, 1997; S. Kauffman & Levin, 1987; S. A. Kauffman & Weinberger, 1989). Therefore, each particular element makes a fitness contribution which, in turn, also (partly) depend upon the specified combinations, among $2^{(K+1)}$ of the presence or absence of the $K+1$ traits which bear upon its fitness. Now, these fitness contributions have to be specified. This procedure is done through the implementation of a matrix of all possible combinations in the N -dimensional binary space and their corresponding fitness (Bocanet & Ponsiglione, 2012; S. A. Kauffman, 1993). So, the fitness landscape is then created by randomly assigning values to the $2^{(K+1)} \times N$ fitness values. Having assigned all the fitness values, we can define the fitness of an entire genotype and specified string of possible x_i within X . Kauffman's NK-model specifies the overall fitness value F of a string x with N loci as the mean of the fitness values f_i of each element with two (binary) possible alleles at each position i :

$$F(x) = \frac{1}{N} \sum_{i=1}^N f_i(x_i, x_{i_1}, x_{i_2}, \dots, x_{i_K}).$$

Where $\{i_1, \dots, i_k\} \in \{1, \dots, i-1, i+1, \dots, N\}$. x_i now is a value of bit i within solution x . Following this logic, fitness values f_i drawn from a uniform distribution ranging from 0 to 1 (S. Kauffman & Levin, 1987; S. A. Kauffman & Weinberger, 1989), thus, take on a different value when a particular element i changes or when another element changes and thereby epistatically affects element i (Altenberg, 1997).

Following the logic from Kauffman's NK-model, a strategic change is assumed to be a process of moving from one firm strategy to another in search of an improved fitness (Daniel A Levinthal, 1997; Daniel A. Levinthal & Warglien, 1999; McCarthy, 2004). An 'adaptive walk' performs this search (S. A. Kauffman, 1993). In essence, what this means, is that if you would (randomly) initially select a point in the landscape, e.g., 001, there are now in total three 1-mutant neighbors, thus directly connected to this particular point in the landscape design (S. A. Kauffman, 1993).

METHODS

Simulation Model and NK-Model Parameters

All included dimensions that comprise ITDCs are based on past empirical and validated work. Hence, this chapter adopts five elementary dimensions of ITDCs, i.e.: (1) sensing (SEN), (2) learning (LRN), (3) coordinating (CRD), (4) integrating (INT), and (5) reconfiguring (REC) (Mikalef & Pateli, 2017; Mikalef et al., 2016; Pavlou & El Sawy, 2011; Protogerou, Caloghirou, & Lioukas, 2012) with each capability having two allelic values, i.e., '0' or '1'. The respective weights of the ITDCs in their contribution to fitness have to be specified. In the original NK-model, Kauffman assumes that all elements of the system weigh equally in their fitness contribution. In practice, however, this does not necessarily have to be the case as specific levels of complementarity among the capabilities may be present under different circumstances. This view is also empirically supported by (Fan & Lee, 2012; Valente, 2008). In light of this shortcoming of the original NK-model, the model parameters are extended with 'unequal' known weighting factors (φ) based on validated empirical work that reports path or regression coefficients of the individual capabilities (Mikalef & Pateli, 2016, 2017), see Table 1.

Table 1. Path coefficients of the weighted model; *** $p < 0.001$

IT-enabled dynamic capabilities	SEN	LRN	CRD	INT	REC
Path weights (β_i)	0.226***	0.249***	0.212***	0.212***	0.245***

As suggested by (Fan & Lee, 2012), one can now assign the different weighting factors ($\varphi_1, \dots, \varphi_5$), as φ_i being equal to β_i divided by the sum of all path weights. Note that the φ_i are appropriately weighted relatively to all the other capabilities, although the weights do not differ significantly. The overall fitness formula is adjusted accordingly (note that the factor $1/N$ now is absent because the φ_i by definition already sum up to 1):

$$F(x) = \sum_{i=1}^N f_i(x_i, x_{i_1}, x_{i_2}, \dots, x_{i_k}).$$

As a final step, random fitness values, f_i within the NK-model need to be specified. f_i is dependent on $K + 1$ binary variables, so there are $2^{(K+1)}$ different inputs. This study determines the corresponding outputs by assigning a value from a random variable that is uniformly distributed on $[0,1]$. For this, the RAND() function is used in Microsoft Excel 2013, and we represent f_i in table form. Now, that this study includes five ITDCs, $2^{(K+1)} * N$ ($N = 5$) table entries have to be generated. This set-up works for all integer K -values and thus for the simulation runs for $K = 0, \dots, 4$ in this study. Once the fitness landscapes have been specified, they remain fixed.

Proposition Development

Firms achieve fitness gains through varying levels of interdependency among the different ITDCs. Synergies only arise among the capabilities when they exhibit a degree of mutual interdependence and thus not when they are completely independent (i.e., $K = 0$). In the case of a fully connected model, the associated fitness landscape is entirely random (S. A. Kauffman, 1993; Weinberger, 1991). Also, the expected fraction of fitter neighbors falls by half at each adaptive step (S. A. Kauffman & Weinberger, 1989). Thus, when the level of K increases, it seems that more and more conflicting constraints emerge and frustration sets in (S. A. Kauffman & Weinberger, 1989).

Research has shown that for intermediate levels of K , the fitness landscape usually contains several local optima, but less than in the case of a maximum complexity scenario, i.e., $K = N - 1$ (Frenken, Marengo, & Valente, 1999). Kauffman (S. A. Kauffman, 1993) in general showed that fitness values of local optima of low- K systems are highest on average. This outcome leads us to believe that the interdependencies between ITDCs are the strongest (and lead to the highest fitness values) if the number of epistatic relations is relatively small. Another striking insight from Kauffman's simulations is that in the case of $K = 2$ (with differing values of N), the highest optima on the fitness landscape are nearest to each other and on average obtained fitness values are the highest (S. A. Kauffman, 1993). Low K -valued configurations (or systems), therefore, enjoy at least two evolutionary advantages over systems with high K -values (Frenken et al., 1999; S. A. Kauffman, 1993). First, local optima obtain, on average, higher fitness values. Second, and even more important, is the fact that the (correlated) structure of their landscape and the large basins of attraction of good local optima make firms more likely attain high fitness levels in lower K -systems (Frenken et al., 1999). Therefore, a low K -value that epistatically connects ITDCs is expected to outperform higher K -value configurations. Hence, we postulate:

Proposition: *Too many ($K = N - 1$) and too little ($K = 0$) epistatic links and interdependency among the ITDCs will inhibit overall fitness in comparison to a simple, non-complex level of epistasis; In other words, a configuration of $K = 2$, on average, will outperform all other K -values in terms of fitness values.*

ANALYSES AND RESULTS OF NK-MODEL SIMULATIONS

Simulation Analyses

In comparison with other NK-studies in the field of management and IS, this study ran our model using various values for the specified parameters. While keeping N constant because of our construct, i.e., ITDCs contains five underlying capabilities, this study varied with values for K .

As our model is probabilistic and dynamic, many runs are needed to ensure significant results (Ganco & Agarwal, 2009). Therefore, we performed 5 runs of 10,000 simulations, i.e., 50,000 simulations, for

each value of K , i.e., $K = 0$, $K = 1$, $K = 2$, $K = 3$ and $K = 4$ to average out random effects (Ghemawat & Levinthal, 2000). The generated data points in the fitness landscapes need to be searched and analyzed to test our proposition. Adaptive walks vary dramatically as the ruggedness of the landscape varies (S. A. Kauffman & Weinberger, 1989).

This study employs a local search strategy² (Nickerson & Zenger, 2004) that aligns well with one's intuition of what in practice such a search process would look like. The search strategy explores the associated neighborhood which we define as those forms or IT-enabled dynamic capability combinations that vary from the firms' current one by only one attribute (Daniel A Levinthal, 1997).

Hence, considering now that N capabilities have been included, a firm now has N different solutions in its immediate neighborhood. When, by randomly picking one of these, a higher fitness level is encountered, the search comes to an end, taking for granted that, on average, a modest performance level might be acquired (Daniel A Levinthal, 1997). This limitation can be addressed by incorporating 'long jumps,' i.e., distant search efforts on the fitness landscape, although, this strategy does not adequately exploit past obtained experience. Therefore, this search strategy is likely to result in a deterioration of performance (Daniel A Levinthal, 1997).

Core Results

The main findings from our extensive simulation runs are now reported. Figure 1 shows the average fitness values for the 50,000 runs per K -value. Hence, fitness values range from 0.67 (for $K = 0$) toward 0.70 (for $K = 2$). An optimum can be seen at the predicted $K = 2$ level. This outcome confirms our proposition and supports the claim that, on average, an ITDC configuration of $K = 2$ will outperform all other K -values regarding fitness. This level of epistasis benefits firms in the process of obtaining higher fitness values and, of course, in such a configuration, the adaptive walk does not get caught in a local optimum.

The lowest obtained fitness values can be seen when looking at the extreme cases, i.e., $K = 0$ and $K = N - 1$. This particular outcome indeed suggests that having too many or too little epistatic links and interdependency among the capabilities will inhibit overall fitness in comparison to a more simple level of epistasis. Clearly, simulation outcomes show that higher fitness levels are obtained with the fully connected model, i.e., $K = N - 1$ instead of the $K = 0$ model. This results could be the effect of having a low N -parameter.

DISCUSSION

Most studies on ITDCs and the process of leveraging IT resources and competencies within firms, do not explicitly state their assumptions concerning the interdependency among the studied capabilities. This development, without a doubt, has contributed to seeming contradictions in IS and management scholarships. From the extant literature, we know that interdependent firm activities are critical sources of performance enhancements. This current research, however, shows that these levels and the degree of mutually reinforcing relationship between ITDCs are conditioned.

This study used a finite number of ' N ' elements, thus the five ITDCs (sensing, learning, coordinating, integrating, and reconfiguring), and a degree of ' K ' complex interactions between those capabilities. The science of complexity was then introduced as a fitting 'lens,' and this chapter highlighted the role the NK-model to study evolution on fitness landscapes on which actors or agents can tune their fitness base on available options and configurations. We departed our research with the knowledge that the avail-

Figure 1. Average fitness landscape values for different K -values

ability of new alternatives among ITDCs reflects a process of (re)combining multiple choices available. This chapter, therefore, extended this fundamental insight and simulated the degree of interconnectedness (K -value) among ITDCs to achieve optimal fitness and drive toward higher levels of competitive firm performance. Moreover, our fitness landscape model provides realistic scenarios with a nexus of possible strategies that can be employed considering a firm's current ITDCs status and interdependency among its capabilities.

Our findings have implications for business and IT managers. First, our simulations outcomes showed that having a non-complex level of epistasis among the capabilities, i.e., $K = 2$ is a crucial source of value through strategic options. Like (Celo et al., 2018; Ganco & Agarwal, 2009), this study highlights that certain levels of epistasis among ITDCs benefits firms considerably in a continuous process of obtaining higher fitness values and enhance firms' competitiveness. Second, the outcomes demonstrate the importance of investing in firms' ability to leverage its IT resources and IT competencies while simultaneously taking into account the diversity of processes and procedures that underlie the ITDCs. Hence, it is imperative for managers to pursue a pluralistic ITDC investment and development strategy. This outcome relates well to the claim made by Ghemawat and Levinthal (Ghemawat & Levinthal, 2000) that 'some choices condition other choices.' This study, thus, guides managers on allocating their firm resources across ITDCs and synchronize them with the degree of internal complexity and environmental turbulence. In doing so, decision-makers should focus capitalizing on substantial IT investments by focusing on maturing and enhancing core areas of the firm, as denoted by the underlying dimensions of ITDCs. This particular aspect raises the need for IT and business decision-makers to form multi-disciplinary teams

including IT and business experts. When executed harmoniously, IT and business representatives are committed and engaged in the process of sensing, seizing and reconfiguring internal and external IT and business competences and capabilities to address the rapidly changing business ecosystem. Third, the synthesis from this current study implies that next to a focus on one specific ITDC—where firms allocate their investments, resources, and assets to, depending on the specific conditions and state of the capability they wish to progress—firms also need to take into account the conditions and enhancement opportunities for two interrelated yet distinct ITDCs. In doing so, firms should follow a process-oriented perspective and focus on those particular activities that are closely related in the value chain. For instance, when a firm lacks competences and capabilities in effectively sensing the environment to spot, interpret, and pursue opportunities and threats, it only makes sense that resources are directed toward revamping existing operational capabilities with new knowledge (i.e., learning capability) and subsequently embed this new knowledge into operational capabilities (i.e., the integrating ITDC). In case a firm experiences difficulties in the deployment of resources, and activities in reconfigured operational capabilities, we suggest that firms first need to focus on synchronizing their assets, resources, and activities (i.e., integrating capability) next to maturing their coordinating ITDC. Also, firms need to direct their coordinating activities to create value to calibrate the requirements for change and to implement necessary business adjustments. There are many other configuration and patterns possible as there are reciprocal relationships among the distinct ITDCs (Pavlou & El Sawy, 2011).

FUTURE RESEARCH DIRECTIONS

Despite this study's contributions, there are several limitations that future work must seek to address. First, this study currently only applied a fixed structure model; that is, environmental factors were not included as well as the influence of collaborative partners/firms modern firms typically have. Current-day organizations need to be able to respond to operational and market adjustments in a swift manner (Tallon & Pinsonneault, 2011) and take external environmental factors into account within corporate IS/IT strategic planning (Newkirk & Lederer, 2006). It could, therefore, be possible that these factors influence the model's outcomes.

Second, our study currently did not extensively discuss the trade-off between short and possible longer adaptive walks leading to specific fitness values. This aspect could have significant implications for business strategies.

Third, an acknowledged limitation of the NK-model (S. Kauffman & Levin, 1987; S. A. Kauffman, 1993), however, is that it uses a binary measure for the interdependency parameter between two components, i.e., K (Fan & Lee, 2012; Li et al., 2006; Valente, 2008). So, an interaction between capabilities is either present or absent. While, in practice, one could argue that interaction between organizational components or entities, and thus also ITDCs, can be reflected by a specific degree of interaction, and is based on the characteristic of the particular organization under study (Fan & Lee, 2012). Therefore, an argument can be made for the additional inclusion of a simulation with a continuous and fractional value in $[0,1]$ as a measure for K .

Finally, our study included only a limited amount of elements ' N ' into our simulation model. In comparison to other NK-model investigations (S. A. Kauffman, 1993; Daniel A. Levinthal & Warglien, 1999; Rivkin & Siggelkow, 2007; Siggelkow & Levinthal, 2003), this amount of interconnected elements is rather small. Avenues for future research could expand the scope and reach of ITDCs and related (op-

erational or zero-order capabilities) and inter-organizational collaboration capabilities and help identify a comprehensive set of business strategies based on the simulation outcomes.

CONCLUSION

Our study is the first to present a fitness landscape model of firms' ITDCs. In this process, statistical survey data were leveraged and used as parameters for a simulation using an extended NK-model. Our contribution, therefore, differs from prior scholarships that use common statistical tools and test the direct or indirect, but isolated impact of ITDCs on competitive performance (Mikalef et al., 2016; Pavlou & El Sawy, 2006, 2011). These results of this study offer several contributions that improve our theoretical understanding of the role of ITDCs and their role in the process of driving toward superior firm performance and extends conceptual and variance based studies on organizational capabilities and ITDCs in particular (McCarthy, 2004; Mikalef et al., 2016). This chapter also demonstrates that the NK-model can indeed be applied toward more general representation problems, as suggested by Altenberg (Altenberg, 1997).

KEY TERMS AND DEFINITIONS

Complexity Science: A scientific umbrella that studies complex adaptive systems (CAS) and has become the de facto standard and holistic ‘lens’ for the analysis and evaluation of complex and nonlinear relations between constituent entities under continuous change.

Fitness Landscapes: Can be considered a model that can be used to describe the particular evolutionary fitness of a system within a particular environment.

IT-Enabled Dynamic Capabilities (ITDCs): Firm’s ability to leverage its IT resources and IT competencies, in combination with other organizational resources and capabilities, to address rapidly changing business environments.

‘K’: K represents the richness of epistatic linkages (term used to describe interacting genes) among N elements.

‘N’: The number of elements that represent the system under study.

NK Model: Provides a comprehensive framework to evaluate the effects of relationships between (N) components of systems and their respective epistatic linkages or relationships (K).

Organizational Capabilities: Firms' potential to achieve specific business strategies and management objectives using focused deployment and are considered the building blocks on which firms compete within the business ecosystem.

ENDNOTES

- ¹ For this research we are satisfied with assuming that firm performance is positively influenced by the level of ITDCs fitness.
- ² Obviously, more advanced and complex search strategies are possible, e.g., long-jumps, directional search and other forms of adaptive walks.

Vertical Integration in Content Provisioning With Cloud Migration

Branka Mikavica

Faculty of Transport and Traffic Engineering, University of Belgrade, Serbia

Aleksandra Kostic-Ljubisavljevic

Faculty of Transport and Traffic Engineering, University of Belgrade, Serbia

INTRODUCTION

The continuous growth of Internet traffic is significantly pushed by emerging high bandwidth demanding contents. All participants in the content provisioning process including content providers, service providers, Content Delivery Networks (CDN) and customers are influenced by bandwidth requirements. Appropriate bandwidth demand estimation and consequently network dimensioning, are of great importance for addressing resource investment. However, peak bandwidth demand varies during the day. Provisioning of self-owned resources that satisfy peak bandwidth demand leads to network underutilization in the periods of low or normal traffic load. Hence, the over-provisioning is cost ineffective. On the other hand, under-provisioning of network resources leads to rejection of customers' requests for service provisioning. Considering all aforementioned, providers in content provisioning process need to consider cloud migration in order to minimize costs and improve Quality of Service (QoS) and hence Quality of Experience (QoE) of their customers. Cloud providers maintain large-scale data centers to offer storage and computational resources in the form of Virtual Machines instances at a relatively low cost. Depending on the characteristics, cloud instances are available at different prices. In general, cloud providers offer three different pricing plans, such as reservation, on-demand and spot pricing.

In order to provide content to the customers, the vertical interconnection between involved providers is necessary. Larger undertakings in content provisioning process often perform vertical integration, thus ensuring a higher control over different segments of the process. Involvement of cloud providers into a content provisioning process introduces additional complexity for choosing appropriate interconnection contract between providers. The vertically integrated content provider's incentives for cloud migration can induce significant changes in interconnection contracts, and consequently in costs and requests' rejection rate. With the aim of obtaining optimal integration charging strategy, concepts like Revenue Sharing, Cost Sharing, and Wholesale Price etc. are applied frequently.

In this chapter different methods of vertical interconnection charging among vertically integrated providers are analyzed and compared. With the aim of QoS and QoE improvement, providers can perform cloud migration. Cloud resources utilization concepts like reservation, on demand, and spot-pricing are analyzed.

DOI: 10.4018/978-1-7998-3473-1.ch072

BACKGROUND

Interconnection refers to physical and logical connecting between involved providers with the aim of provisioning the access to contents, applications or services. Intrinsically, interconnection enables customers connected to one network to communicate with customers of the same or different network. More precisely, vertical interconnection represents interconnection between undertakings on different network's levels. It is a set of legal rules, technical and operational arrangements which providers use to connect their equipment, networks and services. The actors in the content provisioning process often perform vertical integration that is the process of regrouping several segments of the content provisioning process under the control of a single undertaking. Vertical integration can internalize costs for big actors in the content provisioning process, such as global content providers, but also for service providers, which also can benefit from offering their own contents, applications or services. In addition, vertical integration is economical, efficient and it enables achievement of economies of scale (Dai & Tang, 2009). Vertical integration eliminates double marginalization (the effects of market power at consecutive vertical layers) which occurs when undertakings at consecutive layers have monopoly power and each undertaking reduces the output from the competitive level to the monopoly level, leading to overall losses. Also, vertical integration provides better adjustment of supply and demand. Therefore, it improves efficiency, provides more opportunities for profit maximization, and makes innovations more relevant (Maille & Tuffin, 2014).

Vertical integration is a common practice in telecommunications (often form is bundling content and access into a single service). Google is one of the most well-known examples of vertical integration. Initially, Google offered its search-engine service, generating revenues through advertizing. Afterwards, Google expanded the range of services, offering e-mail services, Google Calendar, Google Earth, the browser Chrome, and the operating system Android. The aim was to incorporate Google search tools into the services in order to generate more advertizing revenues, to increase competition at those service levels, and to reduce costs for customers. Another prominent example of vertical integration is Microsoft, which provides operating systems, but also commercializes software included in the Windows Office suite, search engine Bing, and other hardware devices. Apple also performs vertical integration, combining hardware (computers, iPhone, iPad, iPod) and software services (operating systems, Apple Store).

Content providers may perform vertical integration along the process of content provisioning. Big content providers may establish their own hosting capabilities, deploy their own network infrastructures or may provide CDN services themselves (BEREC Report BoR (12) 130, 2012). If a content provider is large enough, vertical integration is an economically viable solution. Additional costs from the establishment of vertical integration are compensated by enhanced economies of scope. Also, the QoS and QoE of the content provisioning process are improved. Some issues of the vertically integrated content provider in content provisioning process are analyzed by Mikavica & Kostic-Ljubisavljevic (2016), Mikavica, Kostic-Ljubisavljevic & Radonjic Djogatovic (2017) and Mikavica & Kostic-Ljubisavljevic (2018a). Often applied contracts of vertical interconnection between vertically integrated content providers and service providers are Revenue Sharing, Cost Sharing and Wholesale Price.

Instead of explicitly defined interconnection tariffs, operators often apply Revenue Sharing, which establishes a fixed revenue share among providers. This type of contract is characterized by operational simplicity, and it can rebalance providers' returns when retail prices are distorted for any reason. Some of the greatest challenges that providers are dealing with are increasing the profitability of the offered services, assuring higher charges for improved services and obtaining a fair share of the increased revenues. A fair Revenue Sharing contract based on the weighted proportional fairness criterion is proposed

by He & Warland, (2006). They also show that non-cooperative strategies between providers may lead to unfair distribution of profit and may even discourage future upgrades to the network. Modeling of non-cooperative interaction between service providers and content provider as a Stackelberg game is performed by Wu, Kim, Hande, Chiang & Tsang (2011). These authors propose Revenue Sharing contract between service providers that jointly provide network connectivity between the content provider and customers. They introduce profit division factor into the contract with the aim of social profit's maximization. Revenue Sharing contract between the content provider and two service providers under network neutrality debate is observed by Coucheney, Maille, & Tuffin (2014). In this model, service providers enable direct connectivity to a fixed proportion of the content and compete in terms of price for customers. Relations between service providers are established using Revenue Sharing contract in order to maximize customers' welfare.

Revenue Sharing and Cost Sharing contracts are often formulated using Shapley value (Lee, Jang, Yi & Cho, 2013; Bogomolnaia, Holzman & Moulin, 2010). This mathematical method allocates resources according to the contributions of each party in a fair manner. Application of Shapley value in order to obtain a proper revenue distribution between content and service provider with elastic and inelastic demand is proposed by Ma, Chiu, Lui, Misra & Rubenstein (2008). The following formulations of Cost Sharing contract in backbone networks: volume-device, 95th percentile-device, 95th percentile-customer, customer peak-device, aggregate peak-device and Shapley-device, are analyzed and compared by Gyarmati, Sirivianos, & Laoutaris, (2012). The results show that Shapley-device contract better reflects the costs of the customers and improves fairness compared to other observed contracts. The key characteristic of Cost Sharing contract is enabling compensation for the costs that the provider incurs in carrying traffic generated by other providers.

Under the Wholesale Price contract, the service provider's payment to the content provider for content provisioning depends on the established wholesale unit price and the traffic volume. The process of determining wholesale prices for mobile virtual networks operators and relations among vertically integrated incumbents when downstream entries are present under the Wholesale Price contract is described by Song (2010). It appears that the wholesale price can be the lower limit of the retail price and determines the competitiveness of mobile virtual networks operators. Related regulatory issues have also been considered and it emphasizes the fact that regulators should have a long-term perspective for the market.

In order to improve content provisioning process and assure satisfactory QoS and QoE, bandwidth demand estimation is essential. Content requires a certain minimum bandwidth which assures that customers' experience in content provisioning is satisfactory. Also, the content has assigned content popularity factor, addressing the probability of access to certain content. In bandwidth demand estimation, parameter depicting content popularity is an important parameter and has to be included in the network dimensioning process. Contents' differentiation according to its' assigned popularity is of great importance for load balancing, as well (Janaszka, Bursztynowski, & Dzida, 2012). Several observations on the suitable content popularity distribution can be found in the literature: Zipf (Zipf, 1932), Zipf-Mandelbrot (Tang, Fu, Cherkasova, & Vahdat, 2007), stretched exponential (Guo, Tan, Chen, Xiao, & Zhang, 2008), Zipf with exponential cut-off tail (Cha, Kwak, Rodriguez, Ahn, & Moon, 2007), etc.

In general, demand has stochastic characteristics. However, it appears that Internet traffic exhibits similar daily patterns and similar peak values every day. Demand attains the highest value in the evening hours, whereas the lowest demand occurs in the early morning hours. Provisioning capacity that satisfies total bandwidth demand is not economically efficient. Hence, the content provider's resources would be idle most of the time. In order to avoid over-provisioning, servers' capacity might be constrained

by parameter determining the portion of the peak bandwidth demand. The adequate bandwidth of the content provider's resources is from 40% up to 60% of the peak bandwidth demand (Li et al., 2011). Intuitively, the less capacity provisioned, the fewer resources are underutilized. However, this situation leads to greater rejection of customers' requests for content provisioning and hence, it must be taken into consideration. A promising solution for this challenge is cloud migration. Providers' incentives for partial cloud migration are analyzed by Li, Zhong, Liu, Li, & Xu (2011). A generic framework that facilitates cost-effective cloud migration of live streaming applications is provided by Wang, Liu, Chen, & Wang (2016). Cost-minimizing framework for migration of content distribution services into the cloud is presented by Qiu, Li, Wu, Li, & Lau, (2012). Costs for partial cloud migration and providers' profits obtained under different vertical interconnection contracts between the vertically integrated content provider and service provider are analyzed by Mikavica & Kostic-Ljubisavljevic (2016).

Cloud resources are organized in the form of different types of Virtual Machine instances. Instances are available at different prices, depending on the applied cloud pricing plan. Two cloud pricing plans that are widely implemented among cloud providers are on-demand and reservation. On-demand pricing plan considers payment only for utilized resources, charging a fixed rate per billing cycle, usually on an hourly basis. Cloud instances are available for an indefinite time. However, the cloud provider retains the right to terminate a cloud instance. Unused time (less than an hour) whether end user or another provider terminated connection, charges as a full hour. If the instance is terminated by the cloud provider, particular unused time is free of charge. Reservation cloud pricing plan enables reservation of cloud resources for a certain period of time, usually a year or three years. Beside upfront fee for resource reservation, cloud provider's customer pays discounted hourly resource usage price. Reserved resources are available at any time on request. Cloud pricing plans' classification is presented by Kansal, Singh, Kumar, & Kaushal, (2014). Spot pricing has emerged as a promising solution for the enhancement of the cloud provider's resources utilization and decreasing prices for cloud customers. Even with resources reservation and on-demand instances' utilization, some cloud resources remain in an idle state. Thus, cloud provider offers its available resources, namely spot instances, in cloud market at a lower price with the ability to terminate instances when needed. Spot pricing presents a dynamic pricing mechanism based on auctions (Toosi, Vanmechelen, Khodadadi, & Buyya, 2016) and reverse auctions (Roovers, Vanmechelen, & Broeckhove, 2012). Different auction-based pricing and allocation mechanisms for cloud resources are proposed (Kumar, Baranwal, Raza & Vidyarthi, 2017; Baranwal, Kumar, Raza & Vidyarthi, 2018; Lu, Yu, Zhu, Li, 2018). Cloud customer creates a bid, representing maximum price willing to pay for a specific instance. The access to spot instance is enabled as long as the bid exceeds the cloud provider's last computed market clearing price. A variant of spot instances, spot block instances can run continuously for a finite duration up to 6 hours. Pricing of spot block instances depends on the requested duration (full hours, up to 6) and the available resources. Prices for spot block instances are usually 30% to 45% less than prices for an equivalent on-demand instance (Amazon, 2018). When cloud customer submits a bid, it is necessary to specify the maximum price willing to pay per hour along with the duration (the number of hours that spot block instance will run uninterrupted). If there are enough available resources for the requested duration, spot block instance will be initiated and run continuously, without termination, for a flat hourly price. This cloud pricing plan is a cost-effective solution for occasional workloads requiring an uninterrupted run in duration up to 6 hours (Mikavica & Kostic-Ljubisavljevic, 2018b). Resource allocation and cloud pricing plans are closely related (Pal & Hui, 2013). Revenue maximization along with optimization of capacity allocation under different cloud pricing plans may be achieved by means of admission control (Toosi, Vanmechelen, Ramamohanarao, & Buya, 2015). Dependence of costs of a vertically integrated content provider from applied cloud pricing plans in content provisioning process

with partial cloud migration is addressed by Mikavica, Kostic-Ljubisavljevic & Radonjic Djogatovic (2017). Optimal placement of contents into the data centers of the vertically integrated content provider and cloud provider is analyzed by Mikavica, Markovic & Kostic-Ljubisavljevic (2018a).

RELATIONS BETWEEN VERTICALLY INTEGRATED PROVIDERS IN CONTENT PROVISIONING

The comprehensive growth of Internet traffic is caused by emerging high bandwidth demanding contents such as video on demand, High Definition Television (HDTV), real-time video, online gaming, file sharing and cloud computing. Participants in the content provisioning process include content providers, service providers, Content Delivery Network (CDN) and customers. Generally, these participants may perform different combinations of functionalities depending on whether or to what degree an operator's business model implies vertical integration (BEREC Report BoR (12) 130, 2012).

Content providers' main functionality is content creation and aggregation. In addition, content providers establish their own hosting capabilities or deploy their own network infrastructure. Content providers encompass various players such as: platforms enabling transactions (e.g. Amazon, eBay, etc.), social platforms (e.g. Facebook), search engines (e.g. Google, Bing), live and on-demand radio and video services (e.g. broadcasters), entertainment services (e.g. Youtube, Dailymotion, etc.), application providers (e.g. Skype), video on demand (e.g. Netflix).

Generally, term service provider refers to operators selling broadband access and connectivity to the Internet at the retail level and at the wholesale level through transit and other forms of integration. These providers enable connectivity for different types of customers, whether it is end customer of content provider.

CDNs serve as aggregators of content on behalf of content providers. Their function is delivering content closer to the terminating network. CDN is a system of servers, placed at various locations at the network edges in order to enable efficient access from any customers' location. Customers' requests are redirected to the servers nearest to them. Different services provided by CDNs are targeted at the different types of content, such as video services, game services, software distribution updates, which content providers distribute. Each type of content has its own characteristics, such as data volume, upstream and/or downstream traffic, peak traffic, for which different CDNs can provide added value.

Term customer refers to both residential and business customers of broadband access in their function of passively consuming content. Generally, customers form downstream traffic volume in consuming the content provided by the content providers. Overlapping between customers and content providers is possible. Players that predominantly act as customers may, in certain situations, act as content providers and provide content and services or applications, e.g. Youtube videos, Internet blogs, etc. Retail customers are private households whereas business customers may range from small to large business and industry customers.

If partial cloud migration is performed, vertically integrated content provider stores all original contents in self-owned servers and serves a major part of the customers' requests for content provisioning. A certain part of the content provider's contents is migrated to the cloud resources provided by the cloud provider. Cloud provider is a party which provides cloud services and performs activities necessary to ensure delivery to the cloud customers as well as cloud service maintenance. Term cloud service refers to one or more capabilities (application, infrastructure or platform capabilities type) offered via cloud computing invoked using a defined interface (ITU-T Recommendation Y.3500, 2014). In order to ensure

satisfactory QoE, cloud provider delivers contents to the cloud CDN. Subsequently, cloud CDN delivers contents to the service provider using a global network. In the periods of low traffic load, the content provider's resources can satisfy overall demand so data transfer through cloud CDN is not significant. However, in the periods of high traffic load, cloud CDN serves meaningful data volume. In order to assure access to the most popular contents, content provider occupies cloud storage capacity according to an appropriate cloud pricing plan. When demand exceeds the capacity of the vertically integrated content provider's resources, customer's request for content provisioning will be accomplished if required content is being stored into the cloud. Otherwise, the customer's request for content provisioning is being rejected. Therefore, determination of the portion of the contents' replication on the cloud has a direct impact on requests' rejection, especially in the periods of high traffic load. In order to minimize the risk of content unavailability, it is recommendable that cloud migrations occur in the period of low traffic load, so the content uploading to the cloud would not additionally load the system. Content replication during cloud migration assures that most popular contents are available even in the periods of high traffic load and it lowers the number of rejected requests for content provisioning. The least rejection rate attains for the greatest content provider's capacity and the greatest portion of cloud migration.

Each provider aims to obtain the highest profit along with satisfactory QoS and QoE which, in the long term, assures customers' loyalty. In general, providers' profits can be obtained by deducting corresponding costs from revenues. Service provider's revenue generated from the customers depends on the retail price and number of customers. Their costs largely depend on the selected integration contract. Prerequisite for selecting optimal vertical interconnection contract between the vertically integrated content provider and service provider is appropriate bandwidth demand estimation. In the context of partial cloud migration, vertical interconnection is being established among vertically integrated content provider and service provider. Relations among content and cloud provider are in accordance with the cloud pricing plans. Which cloud pricing plan will be chosen depends on the costs' prediction, demand, content provider's self-owned capacities and tolerance for requests' rejection rate. Vertical interconnection contracts that are often applied between providers are Revenue Sharing, Cost Sharing and Wholesale Price. Formulations of previously mentioned contracts used in this chapter are provided by Yoon, Yoo & Choi (2010).

In order to enable their customer's access to certain contents under the Revenue Sharing contract, the service provider shares its revenue with the vertically integrated content provider. Hence, the content provider's revenue under Revenue Sharing vertical interconnection contract depends on the service provider's revenue and on the parameter determining revenue share among them. The parameter depicting revenue share among providers is a predefined constant value in the range $(0, 1)$. Greater revenue share assures greater revenue for the content provider. The opposite state is valid for service providers.

Similarly to the Revenue Sharing contract which defines how revenues of content and service provider are shared, Cost Sharing contract defines how costs in content provisioning process should be shared among providers. Extensive analysis of content and service provider's costs in the content provisioning process will be presented later. The parameter defining cost share is a constant value in the range $(0, 1)$. A higher value of this parameter provides greater revenue for the vertically integrated content provider. In addition, content provider's revenue under Cost Sharing contract depends also on profit margin which indicates a provider's profitability and takes values in the range $(0, 1)$.

The parameter profit margin coexists in the Wholesale Price contract with the same characteristics as in the Cost Sharing contract, as well. Hence, greater values for profit margin implicate greater vertically integrated content provider's revenue. Considering the fact that the same parameter coexists in Cost Sharing and Wholesale Price contracts, these contracts are easy to compare.

Content and service provider's costs are highly influenced by a selection of proper vertical interconnection contract. Service provider's costs can be divided into the cost for customers' requests provisioning and vertical interconnection payment to the vertically integrated content provider. The number of the customers' requests provisioned through cloud CDN depends on the portion of contents' replication on the cloud. Hence, partial cloud migration introduces additional costs. However, cloud migration has numerous short-term benefits including lower requests' rejection rate and long-term benefits which consist of customer's loyalty improvement. Analysis of vertically integrated content provider's costs indicates that enhancement of self-owned resources increases costs, which is the primary motivation for cloud migration. The appropriate combination of the vertically integrated content provider's self-owned resources and the amount of cloud migration should be selected in accordance with the realized profits depending on interconnection contracts between content and service provider. Vertically integrated content provider's costs in content provisioning with partial cloud migration can be divided into costs for serving part of requests for content provisioning from self-owned resources and costs for cloud assistance. Cloud instances are being occupied depending on the following factors: estimated future demand, necessary storage capacity for the desired portion of the most popular contents on the cloud and offered cloud pricing plans. Hence, content provider's costs for renting cloud resources consist of: cost for reservation, if resource reservation is enabled; costs for resource utilizing, expressed as a fixed rate per billing cycle if on-demand or spot instances are being utilized and costs for data transfer from cloud CDN to the customers. Cost for content provisioning from cloud CDN to the service provider's network is based on the transferred data volume.

Vertically integrated content provider's profits under Revenue Sharing vertical interconnection contract increases with revenue share enhancement. Greater content replication on cloud increase costs. Self-owned capacities enhancement increase costs, as well. Profit margin assures a certain amount of content provider's revenue. In addition, cost share has a considerable impact on profits. Greater profit margin provides greater profits. Likewise, greater cost share leads to greater profits. However, under Cost Sharing and Wholesale Price contracts, unlike Revenue Sharing, increasing of self-owned resources and content replication to the cloud has a minor impact on profits (Mikavica & Kostic-Ljubisavljevic, 2016). Considering the service provider's profits under different vertical integration contracts and different levels of cloud migration it is notable that higher values of revenue share, cost share or profit margin decrease profit.

Analyzing requests' rejection rate, costs and occupied resources under vertical interconnection with the vertically integrated providers, it is notable that cloud migration is preferable. However, vertically integrated content provider is imposed on additional costs. Considering that less popular contents are not likely to be requested, complete contents' replication on the cloud would be cost ineffective. Hence, partial cloud migration which involves storing the most popular contents on the cloud is a promising solution. In order to achieve the greatest cost savings, appropriate determination of content popularity and demand estimation is essential. Cloud pricing plans in cloud migration may significantly affect vertically integrated content provider's costs, which in turn, may affect the proper selection of vertical interconnection contract with the service provider. Costs of the vertically integrated content provider in content provisioning, with partial cloud migration, depends on the following cloud pricing plans: on-demand, reservation and hybrid pricing plan, as addressed by Mikavica, Kostic-Ljubisavljevic & Radonjic Djogatovic (2017). If a vertically integrated content provider occupies cloud instances on request and without a long-term commitment, the on-demand cloud pricing plan is applied. The costs of this vertically integrated content provider depend on the marginal cost per request for content provisioning serviced by the observed content provider, the total number of billing cycles (hours) during

which certain on-demand cloud instance is utilized and its on-demand price, and the cost for content delivery from cloud CDN to service provider's network. When vertically integrated content provider only reserves cloud resources through reservation cloud pricing plan, costs depend on the marginal cost per request for content provisioning serviced by observed content provider, the reservation fee and the cost for content delivery from cloud CDN to service provider's network. The hybrid pricing plan, proposed by Mikavica, Kostic-Ljubisavljevic & Radonjic Djogatovic (2017), involves the combination of reservation and on-demand renting of cloud resources in order to minimize costs and requests' rejection rate. Vertically integrated content provider occupies a specific number of cloud instances for a contractual period and occasionally rents more on-demand instances. On-demand instances are requested only if reserved capacity is insufficient to support provisioning of the chosen portion of the most popular contents for cloud migration. In that case, costs of vertically integrated content provider depend on the marginal cost per request for content provisioning serviced by observed content provider, the upfront reservation fee, the number of reserved cloud instances, the total number of billing cycles (hours) during which certain on-demand cloud instance is utilized and its on-demand price and the number of utilized on-demand instances.

In general, when vertically integrated content provider assures greater self-owned resources, costs are higher. However, requests' rejection rate in all cloud pricing plans is below 5% (Mikavica, Kostic-Ljubisavljevic & Radonjic Djogatovic, 2017). More occupied cloud instances induce costs, but also considerably lowers requests' rejection rate. On-demand pricing plan provides the lowest costs and the highest requests' rejection rate. Reservation pricing plan includes long-term commitment and, in general, provides higher costs compared to the on-demand pricing plan. It can be noticed that the reservation pricing plan assures lower requests' rejection rate. Costs under hybrid pricing plan are similar to those in the reservation pricing plan. In addition, it provides the most appropriate requests' rejection rates, which values are below 5% even for a lower capacity of content provider's self-owned resources. Thus, hybrid pricing plan improves customers' satisfaction, with acceptable costs.

SOLUTIONS AND RECOMMENDATIONS

One of the most important issues in content provisioning process with cloud assistance that content provider should carefully perceive is the dynamics of customers' demand for access to contents. As a solution, a specific model for the determination of customers' behavior in the video on demand system and necessary upload capacity by cloud providers is introduced by Wu, Wu, Li, Qiu & Lau (2011). In addition, the satisfaction of bandwidth requirements is crucial for bandwidth-intensive applications. Optimal bandwidth provisioning strategy, considering both the operational costs and customers' experience, is derived using the Nash bargaining solution by He, Wu, Zeng, Hei & Wen (2013). Along with bandwidth requirements, storage demand and efficient migration of contents across different geo-distributed cloud resources is another important challenge. Wu, Wu, Li, Zhang, Li & Lau (2015) proposed an online algorithm for the accommodation of dynamic demand for access to cloud storage resources.

Moving the whole content provisioning to the cloud is highly challenging due to security requirements, flexibility, potential performance and control issues. However, cloud computing can provide enough elastic resources even for large-scale contents. Netflix, a major video on demand provider in North America is a typical example, which migrates its streaming services, encoding software, search engines, and huge data stores to cloud provider Amazon (Fan, Yin, Min, Yang, Luo, Lyu, Huang & Jiao, 2018).

Vertical integration in the Internet ecosystem may raise several discriminatory concerns. For example, third parties may have uneven conditions on market compared to the vertically integrated content provider and an online platform, since vertically integrated providers may gain an advantage due to superior visibility to customers, or better integration functionalities (Kramer & Schnurr, 2018). Discriminatory issues are also noticed in app stores, e-commerce and search engines since vertically integrated providers often have higher prominence. Therefore, rival providers have a critical impediment for successful competition. However, giving prominence to the vertically integrated provider's own services doesn't have to decrease social welfare. The prioritization of integrated content can likely be justified ex-post since it motivates the integrated provider to undertake higher investments (Kramer & Schnurr, 2018).

FUTURE RESEARCH DIRECTIONS

Revenue Sharing vertical integration contract has proved to be preferable among Cost Sharing and Wholesale Price contracts when partial cloud migration is performed (Mikavica & Kostić-Ljubisavljević, 2016). However, only reservation cloud pricing plan has been observed. Hybrid pricing plan which involves partial resources' reservation and on-demand instances provisioning may decrease costs and reduce requests' for content provisioning rejection, concurrently. The impact of these pricing plans on selection appropriate vertical interconnection contract between the vertically integrated content provider and service provides is subject of further research. Another promising solution for achieving goals of cloud provider's customers, i.e. providers and customers is spot pricing. However, there are some challenges related to spot pricing, including resources' availability and allocation, complexity for customer's understanding, optimal bidding in auctions etc. Migration to Superclouds allows relocation contents from terminating spot instance into the instance in another availability zone, or even on another cloud provider. This can enhance content provisioning process performances. Content placement into data centers of the vertically integrated content provider and cloud provider is an essential issue in content provisioning process with cloud migration. Optimal placement of contents and associated costs need to be carefully considered in future research. In addition to the observation of different vertical interconnection contracts between integrated providers and their comparison, the aforementioned issues will be addressed in future.

CONCLUSION

The aim of this chapter is to present the complex issue of vertical interconnection between vertically integrated providers involved in content provisioning process with possible cloud migration. Undertakings that are concerned include content provider, service provider and cloud provider with the corresponding CDN along with partial cloud migration. It has to be observed in different aspects. Primarily, appropriate bandwidth demand estimation is of crucial importance. The main reason for this estimation is to mitigate all the disadvantages of under-provisioning or over-provisioning of resources. Requests' for content provisioning rejection rate is another relevant parameter since it significantly affects customers' experience in the content provisioning process. Cost allocation and predicted profits are decisive factors in investment for partial cloud migration and selection of appropriate vertical interconnection contract between integrated providers. Considering the fact that providers' main business goal is achieving the highest possible profits, selection of proper vertical interconnection contract is essential. In this chapter,

Revenue Sharing, Cost Sharing and Wholesale Price contracts between the vertically integrated content provider and service provider have been analyzed and compared. Introducing cloud provider in content provisioning process increases complexity in vertical integration issues, but it may offer (some) different optimal solutions in that process. Different cloud pricing plans are compared in terms of costs and rejection of requests for content provisioning. It appears that partial cloud migration can be a cost-effective solution for providing contents with satisfactory QoS and QoE along with minimization of costs of vertically integrated content provider.

KEY TERMS AND DEFINITIONS

Cloud Migration: Storing a portion of the most popular content provider's contents into the cloud resources with the aim of enabling access to those contents whenever capacity of the self-owned servers is occupied.

Cost Sharing: Integration contract which allocates costs to all undertakings in a fair manner. Cost share among providers is defined in accordance with contribution in total costs of each provider in content provisioning process.

On-Demand: Pricing plan which enables cloud providers' customers to pay only for utilized resources per time unit, usually on the hourly basis. Cloud instances are retained for indefinite time.

Reservation: Cloud providers' customers pay an upfront reservation fee in order to reserve cloud resources for a specific period of time. In return, they receive a significant discount on the hourly resource usage price.

Revenue Sharing: Integration contract which defines modality of revenue shares between providers involved in all forms of provider's integration. It is characterized with operational simplicity and possibility of rebalancing the returns of the providers when retail prices are distorted.

Spot Pricing: An auction-like mechanism where cloud providers' customers submit bids, i.e. maximum price they are willing to pay for specific cloud instance. The access to cloud instances is enabled as long as submitted bid exceeds cloud provider's last computed market clearing price.

Vertical Integration: The process of regrouping several segments of the content provisioning process under the control of a single undertaking.

Vertical Interconnection: Physical and logical connecting between undertakings involved in content provisioning process on different network levels, with the aim of providing the access to contents.

Wholesale Price: Integration contract among providers based on the determination of the unit wholesale price for a given service. Demand and traffic volume are highly dependent on defined wholesale price.

Impact of Management Automation on the Processing of Business Information

INTRODUCTION

Presently, the importance of information in companies is increasingly relevant. Information is a necessary and important resource which is generated, through each of the company's processes. The technologies acquired by companies have evolved over time, to become more sophisticated and necessary to achieve competitive advantages. Information systems have progressively become essential in any organisation, because, with regards to them, coordination is made easier among the people involved in it. Therefore, it is understood that the information system of an organisation is the set of people and material means, which allow the information to be available to whoever needs it, when it is needed and in the recognised format (Solana, 2014). An information system will perform the activities of data capture, storage, processing and distribution of the resulting information. It can be said that the main functions performed by these systems according to Arjonila and Medina (2009), will be to: provide information to the top management, collaborate in the achievement of objectives and achieve competitive advantages. They are essential to help managers keep their company in order, analyse everything that goes through it and create new products that place the organisation in a good place. Therefore, companies that use information systems will have a greater component of adaptability to changes and will be prone to the identification of niches in the market and improvements to processes (Laudon and Laudon, 1996).

Managers are responsible for designing the information system in the company and for users to adapt and use it in their work in the best possible way (Ewout and Per, 2018). One of the specific information systems that companies use generally is integrated software such as Enterprise Resource Planning (ERP) systems, which is responsible for planning resources and managing information, whose structured form can meet the demand of the management needs of the company (Benvenuto, 2006).

With this study, we seek to understand the extent to which new information and communication technologies aid the productivity of the company, while on the other hand, to see the great impact that it provokes in industrial relations. To this end, a process of implementation and the use of an ERP in a company has been observed. In addition to this, the study has focused on knowing the satisfaction and utility perceived by users of this system. Specifically, the study was carried out in a company in the winemaker sector located in Jerez de la Frontera (Cádiz, Spain).

DOI: 10.4018/978-1-7998-3473-1.ch073

In order to achieve the proposed objectives, the work was divided into different sections. First, it will explain the importance of information and the basis upon which information systems are based, as well as how they have evolved and the strategic role they play in companies. On the other hand, we delved into a specific information system, the ERP, carrying out a theoretical course on the concept of ERP, as it has evolved throughout history, the process of implementation and the reason for which the company decided to harness it and the advantages of using this type of system. Moreover, observing how its implementation benefits or affects the operation of the company and its employees.

BACKGROUND

The ERP

In the 60s and 70s of the last century, computer systems were introduced in organisations and companies dedicated to software development were founded. One of the biggest impacts carried out by the information systems was in the management of inventories and in the planning of production, specifically in the area of logistics, because thanks to these systems and the appearance of the computer, the management of sales and order distribution activities were facilitated (Orlicky, 1975). The provision of computers and systems capable of handling volumes of information at a speed that had never existed before, gave rise to companies' acquisition of systems such as Material Requirements Planning (MRP) as they were introduced. Companies began to acquire these types of systems to keep track of their activities in a precise manner. According to Cooper and Zmumd (1990), the objective with which the MRP methodology was developed was to replace the traditional information systems of production planning and control.

At the end of the 70s, the concept of MRPII (Manufacturing Resource Planning) was born, considering new processes associated with production, which were; the forecast of the demand, supply and the logistics of delivery. MRP systems evolved to help companies reduce the inventory levels of the materials they used because when planning their production requirements, premium is placed on only on what is demanded, resulting to reduced costs because they bought only what was necessary (Kapp, Latham and Ford-Latham, 2001).

Generally, the company that integrates an information system, seeks to improve its competitiveness, complete its decision-making process with increased productivity, as well as reduce its operating costs and delivery times. Menezes and González (2010) explain that in order to gain competitive advantage through ERP, a period of several years is usually necessary for implementation, which includes: The integration of existing information systems, the adjustment of the organisation with the ERP system, realisation of re-engineering and capacity of system configuration and its integration capacity.

Benvenuto (2006) defines ERP systems, as a global system of resource planning and information management, which in a structured way, can meet the demand of the company's management needs. Its optimisation leverages a firm's absorptive and adaptive capabilities (Groenewald and Okanga, 2019). ERPs are formed by modules that create workflows among different users which avoids repetitive tasks and improves real-time communication between all areas of the company. ERPs are information systems that employ Information Technology associated with business process engineering, for the redesign and integration of business processes and support operations within the framework of company strategy (Menezes and González, 2010). The ERP software plans and automates many processes, with the purpose of integrating information in the company and is responsible for eliminating the complexity of linking the different areas of the business (Hernández, 2006; Groenewald and Okanga, 2019). The article "The

ABCs of ERP” highlights a number of advantages that companies have with an ERP system. First of all, the ERPs offer a follow-up from the client’s request to the delivery of the product and service, thus, providing an advantage in the integration of the information of the clients’ orders.

On the other hand, the financial area requires information that is as appropriate as possible, which becomes difficult when there are different departments with this information. In this case, the ERP systems become useful, integrating the information in a single source and keeping it unified, so that the necessary information can be extracted for each department. In the manufacturing area, ERP systems make it easier for manufacturing processes to integrate the stages by standardising and streamlining manufacturing processes, which shows a significant reduction in time and increased productivity. Another advantage offered by ERP systems is that it minimises the company’s inventory, in order to comply with sales orders and improve the order delivery process. Finally, it is worth mentioning the standardisation of human resources information. Companies with a large number of employees will benefit from this type of system since they require the handling of varied information that allows the correct application of the economic benefits, as well as the benefits of their personnel.

To implement an ERP correctly it is necessary to define the strategic objectives, the commitment of the management and the willingness to structural and cultural change. More so, taking into consideration the information obtained on the account of the customers, suppliers and competitors. That is why it is considered a challenge, for the implementation of ERP, to build an implementation team that knows the needs of the organisation from the perspective of its business processes, to develop projects that take into account the end users of the system (Malhotra and Temponi, 2010). Benvenuto (2006) highlights a series of objectives to carry out the implementation of an ERP system, these are: decision making, optimise the reduction of time and cost and improve customer service. At the time of implementation, we must consider the extent to which the ERP system needs to adapt to the demands of the company. Many companies find it difficult to implement an ERP due to the rigidity it presents and this can cause the organisation to have to adapt to the software rather than the software to the organisation (Arjonilla and Medina, 2009).

The implementation methodology is constituted by a series of phases that must be developed consecutively. The three phases are as follows: (1) First phase: basic ERP, where the company can obtain substantial results, and usually involves between 9 and 12 months, (2) Second phase: it consists of integration with the supply chain, requires between 3 to 6 months and includes the processes that extend the ERP to the width of the supply chain and, (3) Third phase: the corporate integration in which the accounting and financial elements, applications of human resources, sales, logistics, etc. will be implemented. The required time can be from several months to a year. On the other hand, these systems present a series of characteristics in companies which implement them: High-risk complexity, the scope of application, technological infrastructure, changes in organisational processes and the involvement of end users (Díaz et al., 2005).

Small and Medium Enterprises (SMEs) are organisations with less than 250 workers and they present great importance in the world economy. They are the main economic agents and are a global source of growth of the national resource of the economy in any country. Iglesias and Rodríguez (2009) indicate that the flexibility of this type of company is what makes them compete in such a changing environment as the current one, with segmented demand and technological change that enables flexible production. When SMEs decide to implement ERP systems, they expect to achieve a series of operational benefits as a result of the creation and maintenance of a central database in which all the information of the company is stored, since it decreases the redundancy and unconsciousness of data (Khaleel and Alkhaldi, 2017). In implementing an ERP system in SMEs, the team in charge of the implementation should be taking into

proper cognisance. It is considered, essentially, that the team must consist of: director, project manager, project team, users, quality group and consultant.

On the other hand, Duplaga and Astani (2003) point out that large organisations implement ERP systems by modules, while small organisations usually carry out implementations of complete ERP systems. At the same time, in small organisations, the experience of the implementation is valued and the duration of the implementation is shorter, which could imply that the duration depends on the size and complexity of the company (Adam and O'Doherty, 2000; Lecerf and Omrani, 2019). For large, medium and small companies, it is usual to implement standard ERP solutions, marketed by business management software providers. The company can choose to buy ERP modules that it needs from a single supplier, which has the advantages of integration and data exchange between the applications or buy each module from the supplier that offers the best product (Stancu, 2019).

ERP and Recent Technologies

Cloud computing has acquired great importance in the last decade, so there is a huge trend integrating this technology with ERP, emerging what is known as Cloud enterprise resource planning (cloud ERP) (Shivam et al., 2018). Cloud ERP offers benefits such as (1) faster execution, (2) lower costs, (3) greater agility, (4) real-time integration of business processes, (5) less human resource involvement, and (6) helps to manage effective cross-functional operations in a business organization (Maestrini et al., 2017; Meghana, Asish & Rodrigues, 2018). All of this enables companies to compete in changing markets. The global cloud ERP market has grown significantly in the last decade and is expected to continue to do so in the coming years

On the other hand, working in a mobile technology environment has allowed organizations to considerably improve their processes, this results in greater efficiency, increased benefits, faster access to information, improved planning or reduced errors. Working without cabling –with smartphones or tablets- allows more flexibility and mobility. This is what is currently called the third generation of ERP. It becomes an open system with web-based tools, integrated into social networks and using mobile devices that give them greater agility (Mazur, Rakauskas, & Rosa). The use of an ERP in a mobile environment allows users greater mobility, becoming a part of the daily life of employees, streamlining and simplifying processes. In the same way, it becomes an advantage for organizations because mobile technology is easily integrated with ERP, the development of applications is relatively simple and it has a lower cost (Monteiro & Costa, 2016).

ERP in Agriculture Area

Decision-makers in the agricultural sector are constantly confronted with different variables and risks, such as warehouse management, transport cost or weather. The implementation of ERP systems can minimize the risk in decision making in this environment (Haberli, Oliveira & Yanaze, 2017).

In the agricultural sector, one of the greatest challenge is the distribution of products. Crop yields are difficult to predict, and inventories are very difficult to manage due to the heterogeneity of production. In this context, the introduction of efficient systems is necessary. The implementation of an ERP is very effective because: (1) allows the standardization of business processes, (2) improves the accuracy of information by centralizing it in real time, increasing the ability to exchange such information, making it easier to make decisions, (3) allows accurate accounting of stored products, very useful due to the perishable nature of the products, (4) the operational is more efficient and allows traceability, and (5)

improves delivery times due to the exchange of information in real time, as well as show exactly the quality of products (Kim, Jung & Young, 2015).

Although it is true that implementing an ERP in the agricultural area allows companies to generate value (Ruivo, Oliveira & Neto, 2012), it is necessary to know that it is not easy to find ERP specialists. This is a challenge for companies as they must train their employees in the use of the tool (Esteves, 2014). The incorporation of the ERP offers good results; however, it is important to know that there are also some companies that do not reach their objectives mainly due to a bad use of the software (Chou, Lin, Lu, Cahng & Chou, 2014).

The Resistance to Change

To consider the change in an organisation is to refer basically to the human being because if there is no change in the individuals there will be no change in the organisations (Hernández, 2006). Quinn (1997) emphasises that a person can change the system or the company if he uses the systems at his disposal appropriately. The word change can have different meanings, depending on the people involved in it. In the case of organisations, we can differentiate between employees and managers or suppliers and customers. For example, for the suppliers and customers, the change will mean better service. Managers, on the other hand, will take it as an option to reinvent the organisation, and in employees, there could be resistance to change, thus implementing new information systems is considered a problem for them (Mekadmi, and Louati, 2018).

Resistance to change is a very common symptom in individuals when faced with new systems or simply when they do not know what is necessary to successfully carry out the change. Hernández (2006) states that ignorance is often caused by a series of circumstances in individuals, such as lack of dialogue, or having too much information, which generates some rejection by the thought of not being able to change (Ewout and Per, 2018). Among the economic aspects that companies suffer when implementing an ERP system, the training costs of the staff (employees must learn new business processes), the costs derived from the personalisation of the application when it is not adapted to some business process, the integration costs (integrate the ERP with other applications of the company and check its correct operation), cost of passing registered information of customers and suppliers to the new system.

Hong Kim (2002) stressed that the success of the implementation decreases when a certain level of organisational adaptation is exceeded, because, the ERP and the adaptation of the processes are more effective in smaller measures. That is why the management of change could be considered indispensable for implementing processes. Since, as Laguna (2004) posits that the management of change is the knowledge used to ensure that major changes in the system obtain the correct results, in time and costs. The resistance to change can be minimised. As affirmed by Maristany (1998) there are a series of steps to reduce it. These are; verify if the change will get the resources expected, develop a plan, inform the individuals of the change, etc.

ERP SAP AND WINERY COMPANY

SAP is a software provider founded in 1972, a leader in business solutions for all types of industry. It is the most important software company and the third independent software provider in the world. It commercialises a standard and modular solution which boosts supply to different activities or departments within the company, such as; accounting, sales, relationship with customers and suppliers, warehouse

management or production management, amongst others. The company in this study implemented the ERP of SAP with the goal of benefitting, having information support and thus all employees at the time of working have access to the information. This entity dedicated to the production of wines and other alcoholic beverages such as gin and whisky is a large winemaking company of the Marco de Jerez region.

For the company, it turned out to be an important economic strength, likewise the effort in preparing the employees to avoid the greatest possible risk. At the beginning of the implementation, the company carried out a quality test to begin teaching the workers the use of the system. Once the quality of the system improved, the development test was generated, which is useful for the development of the system to make it as suitable as possible for the company. Finally, it is called a productive software, this is the definitive one the company will use as it is the most adapted for its operation, providing ease of work to its employees. To know the satisfaction of SAP users, a field study of the tool the company implemented was carried out as described in the following sections.

METHODOLOGY

To achieve the main objective of this work, a case study was developed in a winery focusing on SAP, since, it is the system the company implemented. To this end, a satisfaction questionnaire was made to the end users of the system, to gather quantitative information to augment the collection of relevant data on the subject of study of the work, as well as an informal interview to managers and users. In this particular case, information was gathered through the following sources: (1) Survey of 50 end users of the system, (2) Informal interview, (3) Participant observation, that is, the researcher was working in the company during the year 2017.

The questionnaire was designed in two parts, in the first place, sociodemographic questions were asked, such as the sex and age of the user. The questionnaire follows with a series of specific questions about the subject of study, specifically, those related to the training they received, the use they put the system to in the performance of their work, ease of use of the system and user satisfaction with the system. The following questions are directly related to the satisfaction of the users; if it was easy for them to face the system from the start and if they received the necessary training for its use. These questions were resolved according to greater or lesser satisfaction, that is, the participants answered 1 = Never and 7 = Always.

To obtain the answers of the users, the online questionnaire was created through Google, which was subsequently disseminated by sending a link through the internal e-mail of the company. Those consulted were chosen with the motive of being workers at intermediate levels of the company, in order to observe their opinion and not only that of managers, it was also sent to all the departments to which they had access to, so as to obtain a greater diversity of answers.

ANALYSIS OF RESULTS

Description of the Sample

In total 55 questionnaires was obtained, with the number of valid responses of 43. A response ratio of 78.19% was obtained, the high rate is attributable to the fact that it is a direct questionnaire. From the answers to these questions, we find that 55.8% of the respondents were women, that is, 24 of the total and

the rest men. The age group with the highest representation in the sample is between the range of 25 and 40 years old (52%), followed by the 41 and 55 years old age (22%). The answers are concentrated in these sections since the representation of workers in the company was included in these ages. Between them, a total of 32 individuals was added. 57% of the respondents were undergraduates and 31% graduates. Users were also classified according to their departments, to obtain a plurality of opinions according to the area which each respondent belongs. Noting that the majority of responses were obtained from departments such as production, accounting, international and operations. Also, the users' experience with the system was consulted, in order to check for any relationship between the months (time) the user had been using the system and the user's behaviour. Due to the fact that the system was implemented in the company in December 2016, it was observed that the experience expressed in months of the participants is approximately 72% of the cases, between 6 and 8 months.

Satisfaction Analysis

28% of users agreed that the system was not easy to learn and only 2 of the respondents, that is, 5% thought the system accessible. Although no respondent declared that it cannot be learned or that the difficulty of the system was very high, it was observed that users think that SAP is a difficult system to implement by themselves and that more training is needed by the workers of a company for them to efficiently work with it. It is for this reason that they were subsequently asked about the training provided by the SAP provider. It should be pointed out that 44% of the participants, together with 16% and 9%, consider that they need more training when a system of complex characteristics is implemented in the company, that is, courses, manuals and specialised people are required within the company, all to help workers through the process of changing the system they are used to for a new one, since it's tough working with a new system.

The next set of the questionnaire consists of 5 questions related to what the system provides users to do their work. First, participants are consulted to find out if they have sufficient access to the information provided by the system, from their respective jobs. In this case, more than 70% of the respondents believe they can access this information easily and are satisfied with the use of this information, as it enables them to perform their work in a simpler way. Next, we wanted to know if the information that the workers use is kept in the system without being lost, as well as, whether participants feel satisfied with the speed the system provides. So users who recognise that they have sufficient access to information, consider that the information with which they work is maintained in the system without being lost. Most participants say they feel satisfied and that the system provides security since the information and work they do is not lost. On the other hand, users of the system feel satisfied with the speed it provides, since, 35% of the participants give a score of 5 and 37.2% score with 6, on a scale of 1-7 are considered high scores. Next, it was asked if the system allowed users to enter the data in a clear and understandable way, with enough windows, menus, fields, etc. To which the participants responded in 45.5% of the cases that they feel satisfied with the explicit manner of the system. As a result of this question, we wanted to know in a more specific way if the system gave the possibility to use it combined with other useful tools in the daily work like Word, Excel or E-mail. Approximately 70% of the participants responded with scores between 4 and 5, considering that they can use other tools in connection with the system for their daily work. Likewise, 11 of the participants are very satisfied with this question, responding that they always use the system in coordination with different tools. Once you know what SAP users think about what it offers in a practical way, you want to find out the use and knowledge the system provides them. For this, two specific questions were asked, we want to know the level of knowledge or information provided by

the system, to understand what users are accessing and if they can easily apply this knowledge in their work. The respondents answered with more than 34%, positively assessing that the system provides them with sufficient knowledge and information, which they will subsequently apply to their respective jobs.

Subsequently, the frequency with which users access the system to communicate the knowledge and information provided by them was asked. So, users who recognise that the system provides them with information, also believe that this knowledge is communicated to their peers through the system, with more than 45% of the participants in favour of this question acknowledge using the information almost always. Noting that 30 of the 44 consulted are those that consider it useful to communicate information to the rest of the company's workers.

To complete the research, users were consulted on their level of satisfaction with the effectiveness of the system, as well as whether the system increases their quality of working life. In the first case, 64% of the participants responded that they almost always or always felt satisfied with the system and that it was useful to them in achieving their objectives. In the second case, the last issue directly related to the satisfaction of the users, which is to know their assessment of the service offered by SAP. In 36% of cases, users recognise that the quality of work life increases when they use the system in their work. In this question, the answers given are equally distributed. Data obtained showed 7% of the respondents never observed an increase in their quality of work, in contrast, 9% of the cases indicated workers who saw a growing increase in the quality of their work with the use of the system.

SOLUTIONS AND RECOMMENDATIONS

ERP systems are consolidated in companies of different sizes and sectors, thus making it possible for their real benefits to be definitely evaluated. However, choosing the right ERP is essential as, on one hand, the adaptations of the software can compromise the advantages of integration and, on the other, it requires having in perspective the needs derived from the strategy (information obtained from customers, suppliers and competitors) (Menezes and González, 2010). Also, for an ERP to facilitate the re-engineering of business processes, it must possess characteristics such as; the scope, configuration capacity of the system and its integration capacity; Different combinations of ERP perspectives can be applied with a view to achieving the required integration in inter-functional processes.

In this context, in order to guarantee the transition from an old system to the new one, it is important to carry out the following actions: a) hardware, software and database test; b) functional test with applied business processes; and c) the start-up in the real environment with specified technical and business performance criteria (Ugrin, 2009). One of the challenges of this phase is to build an implementation team that knows the needs of the organisation from the perspective of its business processes, to develop a project that takes into account the end users of the system (Menezes and González, 2010).

From an organisational point of view, it is important to identify unbalanced structures that tend to force customised adaptation, increasing the cost of modifications and the risk of the project (Soh and Sia, 2004). To avoid the voluntary mismatches between the users it is important to make a proactive management of the change, educating the users in alternative ways of working, hence, make the new system possible.

FUTURE RESEARCH DIRECTIONS

The investigation of how technologies and information systems support organisations to achieve their strategic goals is a huge field for the development of studies for business areas. In this context, the investigation of a specific technology such as the ERP opens a wide range of possibilities. For this reason, it seems important to carry out in-depth studies, using the case method, of the development of the background factors of the success of the ERP implementation, which together with the ERP system, are sources of sustainable competitive advantages. In particular, more studies are proposed to understand in detail: the role of organisational aspects, the impact of change management and how knowledge and learning exchanges lead to better results.

CONCLUSION

The results obtained from the study, as well as the theoretical development of this work, makes it possible to extract several conclusions about the satisfaction and usefulness perceived by the users of ERP systems and how it influences the quality of working life. The importance of an adequate administration of the information resource is increasingly considered in companies. Companies need technical and economic skills to design and develop information systems, which will permanently connect the company with the external information sources they need. Additionally, companies must design an adequate management of internal information, for which they advance studies that deepen the development and implementation of information systems which will lead them to achieve functions such as planning, controlling and supervising operational tasks, and data processing, as well as identify strategic and tactical information of the management level. The managers of companies must take into account the importance of the use of Information Systems and Information and Communication Technologies, in order to improve competitiveness, enabling them to act efficiently in current markets and achieve permanence in the marketplace.

Although it is a global phenomenon, Spanish companies are not unaware of this expansion, as a large number of them in recent times have implemented information systems such as ERP. They have benefited from the reduction and elimination of tasks due to the integration and automation of functions, as well as the reduction of circulation of documents and information on paper, all being registered in a database. The information is registered in the company and all users of the system have access to it, achieving a global vision of the operation of the company and obtaining available and immediate information for decision making. For all the aforementioned, a Spanish company which recently implemented the ERP software was studied for the observation of the reality of the benefits these systems present to users.

The present work analyses the effects of the implementation of ERP systems on the daily work of a group of users. While studying the satisfaction and usefulness of the system, it is observed that the users are affected by the change caused by the implementation of a new system in their work which they find difficult to manage. On the other hand, they have benefited, since the system has given them new knowledge and information in their work and the possibility of communicating it with the rest of the workers easily, without losing the recorded information. Also, the system provides the advantage of using it in combination with other computer tools that allow them to carry out their work. Furthermore, the importance of the time the software has been implemented is reached, since the effects on the productivity are not immediate, so it has been necessary to observe the improvement in the quality of work of users with the use of software over the months. It is worth noting that the people who are less resistant to change in the system and who have greater satisfaction by increasing their level of work

quality are those of the middle-age, with a higher education level. As a result, university education has a positive effect on the implementation of systems, therefore, companies whose managers have more training are most prone to better implementation. It was discovered that managers and employees with more training are less likely to oppose the change of system and are also more positive concerning the implementation in the company. It is concluded that the need for courses and manuals for the end users is fundamental, that is, proper training on the use of the software is important to make their use easier.

With all this, it is clear companies find advantages in the implementation of ERP systems, hence, different sectors now include them, in spite of the economic cost and time required, they look forward to its long-term benefits. Conclusively, the importance of information for companies is evident, therefore, information systems provide them with a strong advantage when it comes to attaining benefits and competitiveness. Companies should encourage the promotion of a culture in which individuals communicate with each other, as well as increase their skills and knowledge and share them with the organisation. Information technologies have become an acceptable resource which helps in the creation and internal accumulation of knowledge in companies.

KEY TERMS AND DEFINITIONS

Competitive Advantage: A company's ability to obtain a better position in the market in which it operates, to defend itself against its competitors and also maintain its customers. It is the quality possessed by the company and its products so that in the same context, consumers or customers decide to select this company among the other potential options.

ERP (Enterprise Resource Planning): Information Systems that automate processes and allow access to the information generated at any point in the organisation. They integrate all the databases and help save costs and time. During implementation, it is necessary to invest in training staff, integration with other applications and the migration and conversion of data.

Implementation of an Information System: Process in which the planned acquisitions and developments are made, putting resources, both technical and human, in operation in a coordinated manner. It is crucial for users to begin to own the system.

Information Systems Re-Engineering: It consists of structuring or transforming old systems into easier to maintain applications, with more pleasant environments and integration into new platforms whether hardware or software.

MRP (Material Requirements Planning): Material planning system, associated with software which programs production and collects inventories. It regulates the quantity and when to procure materials according to the needs of the company. The software can determine the quantity to be produced, the components needed and raw materials to be purchased, in order to satisfy market needs.

MRP II (Manufacturing Resource Planning): It is an evolution of the MRP system that integrates production resources (raw materials, components, supplies, labour, tools, machinery, capital) with other areas such as administration, sales or the commercial area. It is the software which governs work order and materials and it is oriented towards strategies related to the human resources of a company.

Process Engineering: It consists of designing, planning, and making decisions to achieve the most optimal results of the processes. It gathers knowledge, techniques, and strategies for the company to accomplish the best results. It must monitor and give effective solutions during the start-up of the process and operate continuously until the end of it.

Resistance to Change: Lack of adaptation to organisational changes. This happens when a human being refuses to change their habits or become involved in new situations. In an organisation, employees can resist changing ways of acting, methodologies, schedules, or customs, among others.

User Satisfaction: Feelings of like or dislike which a user has when interacting with an information system, towards the benefits that the system generates. These feelings depend on whether or not the system meets the aspirations of the user.

Winery: Construction or building for the production and storage of wine. In Jerez, they are located on high ground with northwest or southeast orientation to avoid insolation and preserve moisture. The soil is earthy, which helps the winery maintain its freshness in summer, being able to water as many times as necessary. The generous wines of Jerez are dry and according to their ageing are classified as Fino, Amontillados, Olorosos and Palo Cortado.

Management Support Systems Type Business Intelligence (BI) and Factors Determining Their Implementation

Jerzy Kisielnicki

Warsaw University, Poland

Anna Maria Misiak

Warsaw University of Technology, Poland

INTRODUCTION

The article contains the concept and analysis of basic types of Business Intelligence (BI) systems and the analysis of critical success factors of BI implementation. It focuses on the analysis of factors determining the effectiveness of implementation and use of Business Intelligence (BI) tools in organizations, depending on the implementation method applied. A particular emphasis is put on the use of agile methods in BI implementation. This article will present a number of arguments to confirm the hypothesis: Agile methods, in contrast to traditional methods, trigger the synergy of factors determining the effectiveness of using Business Intelligence systems. List of determinants of BI implementation and their link to a selected method of implementation will help organizations to use BI systems efficiently at all levels of management: operational, tactical and strategical. Effectively implemented BI will help organizations to prepare a smooth entering to the Industrial Revolution 4.0 (Industry 4.0).

BACKGROUND

Nowadays, Business Intelligence (BI) systems are the most advanced approach to the application of information systems within an organization. There are many different reasons for this, such as: global economy, data growth, the increase in information significance - these force enterprises to focus on a better understanding of their environment and the inner circle of the organization, as well as on the reformulation of their strategies. Companies laboring under an overload of data, which they are unable to process, decide to implement BI systems or modify them. This solution is related to the need of identifying endogenous factors affecting the reception of new BI technology. This is required both by the shifting environmental conditions and the necessity to follow the environment. BI systems have become an indispensable element of the Industry 4.0 breakthrough. Industry 4.0 is related to the integration of the existing independent digital management systems and the creation of intelligent management support systems. The result is a new quality in the implementation of the management processes (Chen et al., 2018), which subsequently places new demands on supporting tools such as BI.

In view of the various features related to the implementation of the 4.0 concept, there are many technical problems associated with the transformation of traditional organizations. As BI can be used at various levels of strategic, tactical and operational management, it can help the organization on three

DOI: 10.4018/978-1-7998-3473-1.ch074

Figure 1. Phases of BI (Eckerson, 2011)

levels of this transformation: identification and preparation, transformation process and implementation, continuous improvement within an already functioning smart organization. At the strategic level, top executives monitor, manage and analyze key organizational performance factors in accordance with the adopted strategy (Eckerson, 2011). Strategic goals supported by BI systems relate primarily to new sales markets, technological investments in production, as well as necessary modifications to the existing business model. The tactical and operational application of BI primarily assumes the enhancement of business processes (Fink et al., 2017). They are usually used to monitor and analyze operational processes in real time, such as production processes, for instance. Even though BI play such an important role, organisations do not use a real power of these systems. One of the reason behind is a weak implementation process which determines the actual usage of BI (Misiak, 2018). This article aims to list factors determining the effectiveness of using Business Intelligence systems and prove that agile methods trigger the synergy between them.

BUSINESS INTELLIGENCE STRUCTURE AND ITS TYPOLOGY

Business Intelligence (BI) covers a broad spectrum of issues such as practices, methodologies or tools related to data analysis. BIs transcribe data into information and knowledge (Olszak, Ziemia, 2012). Technologically, the BI system collects, integrates, analyzes data and then presents the obtained information in the decision-making process (Fink et al., 2017, Chen et al., 2018). The phases of BI performance, according to Eckerson's study (2011), are presented in Figure 1. Data is collected from various sources, then cleaned and unified with ETL tools (Extract, Transform, Load), transmitted to a data warehouse or virtual space, where they are analyzed by established algorithms, and finally the obtained information is presented in dedicated managerial tools.

These tools include reports, interactive dashboards, alerts and operational, graphical user interfaces, operational dashboards, etc. The benefits of BI are often indirect rather than direct. BI allows for a more effective, fact-based decision-making process and provides better quality information compared to those dispersed in various sources. An improved decision-making process based on good-quality information leads to enhanced business performance. Additionally, BI systems offer the possibilities of forecasting, access to real-time information and thus overall cost reduction (Eiskop et al., 2014).

BI systems can be an independent system, only integrated in the architecture of other systems operating in the organization, or they can be a module of Management Information Systems.

In recent years, the amount of data and the need for information has been increasing rapidly - the number of databases, repositories, files, websites and online stores, social media, etc. is growing. The concept of understanding BI remains unchanged, however, BI technology must adapt to changing needs. Therefore, new tools appear among BI solutions that extend the original BI functionalities. These include **Business Discovery**, intended for self-use by users, so-called BI self-service. This BI system allows you to create your own analyzes and reports without preparing OLAP cubes and data warehouses. Busi-

ness Discovery replaces the three layers of traditional BI: data warehouses, analytical tools and a data presentation layer. Nevertheless, any data warehouse can serve as a data source for Business Discovery. Thanks to this type of an analytical system, users can search for any information they need, not based solely on available pre-defined information structures.

Other tools that develop traditional BI are tools that support Big Data. According to the definition of Provost and Fawcett (2013) **Big Data** is a term referring to large, variable and diverse data sets, the processing and analysis of which is difficult and requires new technologies. In the report by Laney Douglas (Gartner, 2012), Big Data is described according to the 3V (volume, velocity, variety) model. Evolution of Big data brought the model 6V (Enterprise Management Associates, 2017):

- § large amount of data (volume),
- § high data variability (velocity),
- § large variety of data (variety),
- § ensuring the reliability and validity (veracity),
- § data proliferation (vulnerability),
- § data value (value).

Big Data in the technological sense concerns unstructured and process data from newly emerging sources (Devlin, 2013 and EMA, 2017). As emphasized by Power (2014), having Big Data is only useful when they are actually used in analyzes. In the further development of Big Data, *Hadoop* was created - distributed processing on the *open source* platform (managed by the Apache Software Foundation). Hadoop provides enterprises a new opportunity to process data more efficiently - primarily from the cost-side perspective (Rao and Vadapalli, 2016).

The development of tablets and smartphones has created a need to establish **Mobile BI** systems, which in a sense constitute additional functionality offered in BI packages. The availability of BI reports and analyzes on tablets and mobile phones allows access to company information from anywhere (Ronda et al., 2015).

The popularity of the concept of placing IT solutions in the cloud resulted in the creation of **Cloud-based BI**. These are BI systems offered in the Software as a Service (SaaS) model. For BI customers, it is a convenient way to use tools without the need to invest in infrastructure. Along with the development of the company, SaaS services enable the adaptation of BI infrastructure and software (Howson, 2013).

Rapid evolution of information technology and advanced production technology require the usage of BI systems. Production enterprises increasingly require support of Artificial Intelligence. Deterministic-digital models are replaced by heterogeneous models (Stochastic - deterministic). Due to the new challenges, the information needs of the traditional manufacturing industry have been gradually reduced. Decision systems are becoming more and more complex. BI systems, especially the ones of new generation, support integration processes of previously independent discrete systems and use more complex technologies. Intelligent production technology is one of the fields considered to be in the high technology class. Indeed, the industrialized countries pay more attention to it. Proposed by individual countries or organizations strategies such as “Europe 2020”, industrial revolution 4.0, US development programs accelerate the pace of reindustrialization and production flow. Intelligent manufacturing transformations supported by BI systems have an impact on future production worldwide.

In summary, BI systems are used to enhance the efficiency of the decision-making process. BI, transforming data into information, allows managers at all levels to better understand business and make wiser decisions. From the point of view of technological architecture, BI can download data from various

Table 1. BI Typology by data type analyzed (Chen et al., 2012)

	Characteristic	Feature
BI 1.0	Relational database in DWH § ETL (Extract, Transform, Load) - tools for data collection and OLAP (OnLine Analytical Processing) § Dashboards and score cards § Data mining	§ Database based on columns (DBMS) § In-memory processing (DBMS) § Real-time decision § Statistical analysis thanks to data mining
BI 2.0	BI 1.0 enriched with Web-based technology and unstructured content / data § Information (aggregated data) collected and extracted § Answers to inquiries § Analytics and web analytics and web intelligence § Analyzes and analysis of social media	§ Significant information processing § Opinion mining - BI allowing to download information about the mood of users / Internet users about a specific thing (e.g. product) § Answers to questions asked in natural language § Text and content analytics
BI 3.0	BI 2.0 enriched with mobile and sensor technology § Location-aware analyzes (identifying the geographical position) § Person-centered analysis § Context-relevant analysis § Mobile visualization	§ Ability to analyze BI 2.0 on mobile devices

sources - both systems inside and outside the company - and then, through defined algorithms, it presents them in the form of synthetic information. The number of possible data sources, type and amount of data increase, thus it leads to continuous development of new BI functionalities, tools and their new naming. The BI Industry 4.0 breakthrough will combine all the features described above. Technologically, BI will showcase much better performance in order to be able to provide information in real time from any data source and enterprise ecosystem devices.

Typology of BI systems changes dynamically and depends on technology level, the purpose of their use, or the type of data processed. The literature describes many different ranges of available BI systems and their typologies. The most popular is the typology according to Chen (2012), presented in Table 1.

In the era of Industry 4.0, BI systems should meet the features of BI 3.0 extended to learning technologies, real-time analysis of large data volumes (Big Data), and have forecasting functionality (Chen et al., 2018). It should be catalyzed by the evolution of trends like the Internet of things (IOT). From that perspective, BI systems focus less on creating reports that represent well-known situations in the past and more on discovering unknown insights and predictive outcomes about data in the future (Rodriguez, 2016).

THE ROLE OF BI SYSTEMS IN AN ORGANIZATION

BI systems allow making decisions based on information possessed by a company (Kisielnicki, Sobolewska, 2019). Thanks to them, decision-makers can take better and more effective actions and justify them (Davenport and Patil, 2012). The importance of BI has different dimensions depending on business areas in an organization. It can be used for financial reporting, marketing analyzes, management reporting, etc. BI provides managers the information on what is happening in their organization and ensures the easy access to information, often on-line (Williams and Williams, 2010.). For example, in the area of finance and controlling, these may be: analysis of financial statements (assessment of financial and property situation and profits by: index analyzes, causal research, regression and correlation analyzes, etc.), analysis of current assets (index analyzes in the scope of inventories, receivables, cash), analysis

of the capital structure (using the equity and foreign capital ratio), etc., in the area of sales: customer analysis in time (profitability of customers and groups of customers within a specified period of time based on purchases), analysis of deviations in sales of product-varied assortment (impact of the assortment change on the number of products sold and their price), etc., in the production area: analysis of production efficiency (analysis of productivity over time compared to standards depending on the production line, machinery, production operations, etc.), quality analysis (dependence of the quality of manufactured products and the used production lines and semi-finished products by suppliers). By analyzing indicators and deviations from the expected trend, enterprises can more effectively control decisions, accelerate development and increase their profits. Howson (2013) points out, however, that BI can bring an increase in the value of a company if users effectively use it. A wider and effective access to information does not guarantee a better performance of organizations, but rather show how available information is used by organizations. Howson (2007) indicates that BI alone does not introduce any value to a company. Therefore, BI implementation should not be a strategic goal, but a tool to implement management goals.

Business Intelligence can concern every level of management - operational, tactical and strategic. Operational and tactical management is always a consequence of the strategy. Therefore, the business strategy will be the basis for using Business Intelligence. A link between BI and a company's strategy can be presented in three dimensions:

1. BI as a support in creating an enterprise strategy;
2. BI used in the implementation of a company's strategy;
3. a need to implement BI as a result of a company's strategy.

Organizations, in order to set a good strategy, need to conduct a series of surveys in search of an answer to a question what factors and to what extent will affect their activities in the future. Implementation of a strategy requires continuous observation of the environment and analysis of micro- and macro-environment. Regardless of methods or tools used, the input data is required for this. These data will come from various sources, they will often be repeated or will appear in different formats. Thanks to the data warehouse or the logical layer of data processing (virtual warehouse), it is possible to combine data and thus obtain complete and cross-sectional information without the need to manually merge data generated in individual systems. Data warehouses store information about a long time horizon, which allows you to search for trends and use forecasting methods. Both current data analysis and forecasting may be useful in the case of budgets and their verification in various areas, e.g. labor costs, investments, sales revenue, product seasonality, but also competition activities and trends of its growth. Analytical applications often contain pre-defined solutions for a given company area with a standard set of reports and alert mechanisms. The **e-Business Intelligence extras** enable customers, suppliers and other partners to access information quickly. Acceleration of decision cycles has an impact on the efficiency increase, and it can be implemented when both parties have continuous access to information. **BI solutions for e-commerce** are used in advanced traffic flow analysis, tracking of user-customer traffic as well as accurate customer segmentation (Simon, Shaffer, 2003)

Business Intelligence systems support strategic management of organizations and allow them to achieve goals at every level. All levels of the organization base their actions on strategy. The need to implement BI should be the result of strategy - only then tactical and operational actions will lead to its effective implementation. Therefore, BI can allow defining a strategy and its implementation, while the decision to implement it must be the result of decisions at the highest level of a company.

BI IMPLEMENTATION METHODS

In the **traditional approach** to BI implementation, the stage project life cycle is intuitively mapped to cascading. It assumes that each stage of the project can start only if the previous stage is fully completed. Additionally, it is not possible to return to the previous stages after their completion, although there are variations of the model that allow returning to the previous stage in order to modify its partial products (change management in the project). For BI, this means that an organization will have to take into account the long waiting time for a final solution delivery.

This approach has many advantages, such as ease of planning, simplicity and linearity of a project. This method works well in projects where change is not recommended after delivery of certain products. However, using the cascade model in BI projects, numerous drawbacks and limitations should be taken into account. One of the disadvantages is maladjustment of the model to the changes occurring in the project. Changes are the everyday reality of every BI project (Cobb, 2012), especially in the case of systems created from the beginning or any information systems. In BI implementation projects, traditional methods work well for small organizations or limited substantive scope. This is directly related to a shorter implementation time and thus lower probability of changes in requirements. Thus, nowadays, agile approach has started to become popular.

Agile can be defined as a philosophy that focuses on principles, people, processes, products and practices, having a pragmatic approach to business needs (Cobb, 2012). Agile assumes that each project must be consistent with the strategic goals of the organization and focused on the early delivery of real business benefits. Business goals must be understandable for stakeholders who have an appropriate level of authority. A designed solution is delivered in time and in accordance with business priorities. All these assumptions do not differ from the traditional approach, however implementation of these assumptions is different. For this reason BI technology might be more easily accepted by users and lead to better views of information (Hughes, 2013).

There are many opponents of the agile approach, especially for Business Intelligence projects that have been conducted for many years in the traditional project management cycle (Lovell, 2014). In the case of such projects, it seems that many years of experience have allowed to fine-tune traditional methods almost to perfection, educating many project managers and developing many tools, both paid and free (*open source*). It is worth noting that the Agile philosophy has become part of the Industry 4.0 breakthrough. New technologies are implemented in agile way, and more often companies call themselves “agile” (Anderl, Fleischer, 2015).

In summary, agile methods require a change of approach and habits that are the result of running most BI projects in a cascade model. In traditional project management methods, the cost and schedule of a project determines its scope. Agile focuses on business values and uses them to determine a quality of the implemented BI system. Traditional methods are appropriate for a laid-out and predictable environment, while agile methods are ideally suited to the environment of frequent changes, uncertain and without a specific result. In case of BI projects, information requirements may change during a project, and often the information, which was very important, becomes useless at the end of the project. All models resulting from traditional methods adopt so-called *Rational Agent Model*, agile methods are based primarily on so-called *shared value approach* (Cobb, 2015). Traditional methods use and create structures based on control, while agile structures are flat, based on cooperation and so-called mutual inspection.

The choice of project management method will depend on many factors, such as an organization's ability to change, a type of BI project, as well as a size of the project. Table 2 presents main differences between traditional and agile approach.

Table 2. A comparison of Agile and traditional methods (Project Management & Agile Methodologies, 2012)

Approach	Agile	Waterfall
Emphasis	People	Process
Domain	Unpredictable/ Exploratory	Predictable
Documentation	Minimal-only as required	Comprehensive
Quality assurance	Customer centric	Process centric
Process style	Iterative	Linear
Organization	Self-organized	Managed
Upfront planning	Low	High
Perspective toward change	Adaptability	Sustainability
Prioritization of requirements	Based on business value and regularly updated	Fixed in the project plan
Management Style	Decentralized	Autocratic
Leadership	Collaborative, Servant Leadership	Command and control
Performance Measurement	Business value	Plan conformity
Return on Investment (ROI)	Early/throughout project life	End of project life

SOLUTIONS AND RECOMMENDATIONS

The complexity and diversity of BI systems means that the success of their implementation requires a methodical foundation and proven scientific theories. One theory is the theory of critical success factors that provides a good basis and a reference point to know what criteria should be used in BI implementation methods (Olszak and Ziemba, 2012, pp. 136-137). The idea to determine the factors that influence the organization's success appeared in 1961, presented by Daniel, and then developed by Rockart and Bullen (1981), in the context of the Management Information Systems (MIS) design. Noting that management boards of enterprises rarely use MIS systems, they stated that such systems should be structured in accordance with managers' information needs. In order to ensure that information needs of managers are known and included in the MIS management information system, they used the term "critical success factor".

In today's literature, critical success factors focus primarily on IT project management. Many consulting companies have developed their own lists of critical success factors and measures of project success, using them in their services of advisory.

Table 3 presents the critical success factors for projects, in particular BI, collected from four consulting groups. One of them is Deloitte, specializing in implementing IT solutions for business, in particular BI class systems, process and organizational consulting. The other two are McKinsey and Boston Consulting Group, the world's largest organizations specializing in strategic consulting.

The identification and use of factors influencing success is necessary for the proper preparation of selected projects. A precise measure of project activities is *efficiency*, most often directly referring to the financial or performance perspective of tasks carried out in an organization or a specific undertaking.

Efficiency measures can be divided into the following groups: measures of economic efficiency (quantitative) and measures of quality efficiency (Kisielnicki, 2017). Measures of economic efficiency (quantitative): Return on Investment, Payback period, Net Present Value, Net Present Value Ratio, Internal Rate of Return. Often, these measures are used for IT projects, by analogy to typical investment projects.

Table 3. Critical Success Factors of IT projects (especially BI projects) by Deloitte, McKinsey and Business Consulting Group (2016)

Deloitte	McKinsey	Boston Consulting Group
1. Project implements an organization's strategy and its needs 2. Sponsor of the project is the management board 3. Organization of the project - structure and management 4. Allocation of qualified resources to the project 5. Preparation for the project before it starts 6. Method of project management 7. Quality control	1. Sense of ownership and dedication to the implementation project 2. Prioritization 3. Recourses and their competences 4. Responsibility for tasks 5. Continuity in improving project implementation 6. Long-term planning from the first day 7. Effective method of project management	1. Full top management support 2. Project time: project implementation is shorter than 2 months or time between key controls is no longer than 2 months 3. Adequacy of participants' selection: run by a competent, motivated and well-coordinated team 4. Involvement of senior management 5. Commitment at lower levels: a project carried out by people with a positive approach to changes and changes are actually awaited by them 6. Additional effort: achieving, maintaining and consolidating does not require a lot of extra effort from project participants

It is difficult to assess the financial effects of projects with sufficient accuracy and refer them directly to the expenditures incurred. Quality performance measures are a group of measures which assessment is carried out in non-valuable units. They depend on the specific situation and can be divided into such groups as measures related to the organization's strategy in connection to BI implementation, BI project organization, the suitability of BI tool, technical and functional BI aspects translating into organizational benefits resulting from the BI implementation (Chen et al., 2018; Gaardboe and Svarre, 2017; Kisielnicki, 2008; Olszak and Ziemba, 2007). Many researchers have analyzed CSF of BI implementation. Delone and McLean (2003) demonstrated in their research critical factors of BI success: quality of information (obtained from the BI system), quality of the system (including its functionality and ease of use), quality of system maintenance. These factors might be directly translated into the intent of system's use and user satisfaction. As a consequence it leads to net benefits' achievement. In addition, as necessary success factors, they provided aspects of a schedule, budget and scope of the BI system implementation. It is a triangle that should be taken into account for every IT project. Ariyachandra and Watson (2006), on the basis of their research on the factors determining a success of BI implementation, divided them into three groups of CSF: organizational, efficiency of processes and infrastructure performance.

Similar observations have been found out in the research on critical success factors of the BI implementation process in small and medium-sized Silesian enterprises, carried out by Olszak and Ziemba (2012). The authors pointed out three perspectives of critical success factors: organizational, process and technological.

Nommesen and Macfie (2012) added a pragmatic test as a necessary factor for the success of the BI implementation. This applies to the quantitative check of data downloaded from source systems to a data warehouse.

Currently, organizations that decide to implement BI focus their attention on the method of system implementation. Agile methods are the most frequently selected. The Agile BI term is being used more and more often. **Agile Business Intelligence (BI)** refers to the use of the agile software development methodology for BI and helps in adapting to changing business needs. Agile BI enables the BI team and managers to make better business decisions. Agile method works on the iterative principle; it provides the best product. With Agile the requirements and design phases overlap with development, thus improving the development cycles for faster delivery. It promotes adaptive planning, evolutionary development

and delivery, and time-boxed iterative approach, and encourages rapid and flexible response to change. Agile BI encourages business users and IT specialists to think about low Total Cost of Change (TCC). With agile BI, the focus is not on the BI problem in the functionality of the cycle. Many companies fail to deliver the right business management (Loshin, 2019).

Research on determinants of BI implementation (Misiak, 2018), confirmed the results of research of predecessors in terms of both CSF and an impact of method on the effective use of BI in organizations:

- Regardless of the adopted implementation method, the factors of functionality and usability of BI are determinants of intention to use and actual use of BI;
- For project teams that have used a traditional implementation method, determinants of a practical use of BI in tasks at work and simple access to broad and detailed information are a quality of data in BI and simple tool handling. Determinants of the current use of BI are its practical usefulness and the possibility of simple access to detailed information.
- For project teams that have used agile implementation methods, determinants of a practical use of BI in tasks at work and simple access to broad and detailed information are the reporting speed and project management style of implementation, focused on cooperation. Determinants of current use are the suitability of BI system for tasks at work. Teams working with traditional methods also indicated this determinant.
- Very important determinants of BI implementation were also the need for BI implementation resulting from the organization's strategy and integration and mutual trust of team members. The functional aspects of BI were repeated several times in the analysis, these are: an easy access to detailed data (eg drill-down), an easy extension of access to wide information and a possibility of receiving individual content. It concludes that when BI implementation project is planned, in the first place the organization's strategy should be well recognized and understood. Based on the strategy, BI must be adjusted to its actual needs and implementation capabilities through the implementation of subsequent tactical and operational goals. At the same time, it is important to ensure the practical use of BI by future users, even if it involves a frequent change or extension of requirements during a project. At the same time, the manner of project organization and good relations in teams focused on cooperation may have an impact on the willingness to provide a high-quality BI product.

Additional interviews conducted by Misiak (2018) confirmed that for BI implementation projects, a use of elements of agile methods is more effective. The interviews were based on a number of questions that were based on the results of quantitative research and quality measures. The questions have been grouped thematically (Figure 2). Respondents used the Likert scale from 1-5 (where 1 means the lowest grade and 5 means the highest grade) and evaluated organizational issues, according to a current state of BI implemented in their organizations. The interviews' results showed that BI users participating in the agile project provided much better opinion on the implemented BI tool.

The users rated the highest a quality of BI data, indicating this factor as very important from the point of view of the usefulness of BI tool. Data was more complete and accurate when agile implementation methods were used. The usability of BI to work over other available tools was better assessed in organizations that used agile methods. Users associate the usability of BI with the individualization of content. The more the tool can be adapted to their needs, the more useful it becomes. Project management as a determinant of BI implementation was assessed by almost 3 points higher in the case of agile approach. According to the respondents' results, for this factor there is the biggest gap between the assessment of

Figure 2. Assessment of critical BI success factors depending on the applied implementation method according to the respondents' experience (Misiak, 2018)

the project carried out traditionally and agile. In the surveys, the need to implement BI resulting from the organization's strategy turned out to be the most important factor affecting the success of BI. During the interviews, managers indicated the essence of strategy in the BI implementation, at the same time confirming that it is independent from the applied implementation method.

FUTURE RESEARCH DIRECTIONS

The changes taking place are the result of new solutions in Management Information Systems (MIS). These are: Internet of Things (IoT), cloud computing, processing of big data sets (Big Data), blockchain technology, and all types of sensors and communication protocols. Most of these technologies are not exactly cutting-edge innovations. It is the combination of these technologies together with business processes and data processing that constitutes Industry 4.0 (Anderl et al., 2015). The value to be created by the breakthrough of Industry 4.0 will be achieved through innovative products along with the services, their individualization, growing competitiveness and more efficient operational processes. The ongoing progress in ICT (Information and Communication Technologies) enabled the functioning of intelligent, flexible organizations such as, among others, smart factories and smart cities (Schwab, 2016). In particular, Industry 4.0 is associated with a smart factory, where independent machines, systems and people become integrated and are communicating, leading to the creation of self-awareness and self-learning

devices (Lee et al., 2014). This allows for better control of production processes, thus increasing the quality of products (Bagheri et al., 2015), while also ensuring a more efficient acquisition, analysis and use of data, for the implementation of which the BI systems are a prerequisite. We can put forward the thesis that BI is a tool that significantly affects the functioning of an organization, which constitutes an implementation of the Industry 4.0 concept. These systems will have to feature the characteristics of the 4.0 breakthrough, i.e. processing of data from various systems and devices (internal systems, Internet, mobile devices, etc.), cloud processing of large data volumes (Big data), personalized visualizations, cooperativity, forecasting and reporting capabilities in real time and cognitive features. BI in Industry 4.0 will represent Artificial Intelligence (AI) functions or will be the main source of data for AI.

The BI operational capabilities are related to the creation of operational added value, which in turn leads to the creation of strategic added value (Fink et al., 2017). Therefore, it is advisable to measure strategic added value even if only operational BI applications have been implemented. The measurements carried out with the help of BI can be a contribution to the emergence of awareness of the need to implement Industry 4.0, and then to support the enterprise leading it towards the very transformation in the direction of Industry 4.0. The analysis of operational processes may allow to assess the readiness of individual areas for their introduction into the scope of technology 4.0. Furthermore, it can point out gaps and the needs for change prior to the existence of this technology. Data, information and knowledge are located in different places within the organization - they can come both from the inside or the outside, and they can take on various forms and be available on different media. This means that rendering the usefulness of collected information and knowledge in order to implement Industry 4.0 within an organization requires the introduction of its codification and the degree of abstraction - that is, a degree of generality - and the possibility of its use in various activities. Business Intelligence systems support both the registration of codification and the handling of algorithms and filters that allow obtaining knowledge and useful information (Cheng et al., 2019). Therefore, the BI system can be used for transformation by feeding data into a common denominator, and thus for connecting and communicating devices and employees within the network of smart factory operational processes. In a smart enterprise, intelligent logistics and objects, communication of mobile devices, etc., all work thanks to the efficient use of all the resources. Moreover, the goal is the production of smart items that can be further developed, even when they are already delivered to the customer, which can become an active element of the entire production process (Sendler, 2013). The vision thus described requires an independent order and organization of individual treatment of a single customer's order at each stage of the order's execution process (from the receipt of the order to its sending and continuous product modernization). In order to make it possible, Industry 4.0. must cover various forms of information exchange: exchange of information between humans (H2H), human-machine interaction (H2M) and exchange of information between machines (M2M) (Roblek, 2016). According to David et al. (2017), smart products can be characterized and improved by enhancing them with some input dimensions (e.g. sensors and download of relevant data), output dimensions (e.g. displays, including visual, audible or tactile signals), human-computer interfaces (e.g. control and interaction), interoperability (e.g. exchange of information between artefacts), integration (e.g. relevance or system utility on a larger scale) and resource efficiency (e.g. obtaining, generating and saving energy to provide their service) (Dawid et al., 2017). Thus, it can be stated that prior to implementing BI systems, one needs to focus on tasks related to the rapid transmission of heterogeneous information. At the same time, organizational procedures must be supported in the area of obtaining information in real time. Therefore, the effective use of BI in enterprises has become a key element of their strategy for transformation within Industry 4.0 and it will be a topic of next research.

CONCLUSION

Presented literature, analyzes of the researchers and trends in the BI market (Industry 4.0) confirm that agile methods trigger to a greater extent than the traditional methods of factors determining an effectiveness of Business Intelligence systems' usage.

The effective application of BI depends on the following groups of factors: 1) organizational (management support, clear vision, interactive cooperation, team composition, planning, etc.), 2) economic (budget, ROI, range), 3) technical (system quality, flexibility, scalability, data integration, data quality, ease of use, etc.), 4) sociological and psychological (leadership, motivation of the board and team, trust in the team, organizational culture) and 5) legal (aspects of financial and tax law). Among these determinants, there can be distinguished the following, affecting the efficiency of BI applications:

1. functionality of the system, including customization of content and access to more detailed and broader information as well as reporting speed,
2. data quality, their correctness and actual suitability for tasks,
3. usefulness of tools for tasks at work, so that the strategic, tactical and operational goals set by the organization can be realized,
4. method of implementation, especially the focus on cooperation and trust among project team members.

Essential topics discussed in the article introduce the elements of agile methods for BI implementation and an attitude of BI users to independent creation of individual content from large volumes of data coming from many sources. This indicates the need for further BI development in the direction of BI agile, BI self-service and Big Data, thus confirming that BI systems significantly affect the functioning of organizations implementing Industry 4.0. In addition to the many technical challenges that Industry 4.0 is facing, there is a need to identify the current state of business processes by mass reorganization of them so that enterprises and factories can become genuinely intelligent. The maintenance and further development of Industry 4.0 does not limit the need for BI systems. The emerging new data sources will introduce new opportunities to entrepreneurs, and hence they will need data analysis and tools that will provide guidance for new directions of development.

KEY TERMS AND DEFINITIONS

Business Intelligence: Is a broad spectrum of issues such as practices, methods, or tools, with data analysis. BIs transcribe data into information and knowledge. BI can be an independent system integrated with other systems or exist as a Management Information System module.

Industry 4.0: These terms define the next, after the digital economy, stage of evolution of the economic management system. It is presented as integration of existing independent digital management systems and creation of intelligent management support systems.

Project Management Method: Comprehensive project management methods containing recommendations for conduct, pertaining to the entire complex of project management problems and processes.

REA–Semantic Teaching in the Accounting Information Systems (AIS) Courses

6

Roosevelt University, USA

Shamsul I. Chowdhury

Roosevelt University, USA

INTRODUCTION

To meet the evident need for accountants that are familiar and understand Accounting Information Systems (AIS), many colleges added AIS courses or updated their current courses. Such a move was supported by accreditation bodies like the Association to Advance Collegiate Schools of Business (AACSB). But despite the agreement of the importance of AIS courses, the addition of AIS topics to the curriculum followed different approaches; some schools have only one AIS course while others may have two or more courses. Furthermore, most of the AIS courses were created with different topics and without any general agreement on the supplemental concepts (Fordham 2005), one may find some courses that focus on AIS security, audit and fraud while other courses give more emphasis on System Development Life Cycle (SDLC) and database design. Thus, textbook authors and publishers became more motivated to introduce textbooks that cover many of the needed skills, but in a format that exceeds what can be covered in one or even two AIS courses.

One of the important topics that most AIS course designs aim to cover is the REA (Resource-Event-Agent) framework that was designed by William McCarthy in 1982, it is widely adopted in AIS curriculum as a methodology to design a relational database, but despite its popularity the complexity of this topic and time limitations make it challenging to many AIS educators to cover such topic along with all the other learning outcomes that the academic programs and job market expect graduates to have. As a result, many AIS educators are facing a dilemma when they are creating or updating their AIS courses to achieve all the required learning outcomes within the allotted course meetings times. The easiest solution to solve this problem would be adding a second or a third AIS course, but that may not be possible nor practical in many cases. Consequently, some AIS educators ended up considering some topics as self-study material. Such an approach may work, but there is a price to be paid, greater preparation time, and student resistance to novel teaching approaches (Herreid and Schiller 2013).

Some attempts were made to address this issue; Seow and Pan (2017) designed an online self-study tutorial to teach REA at the undergraduate level, their online tutorial was designed to supplement class lectures by reinforcing the concept and incorporating practice to assess the student understanding. The online self-study tutorial helps in reducing the time required to teach REA data modeling, but it does not address how to deal with the theoretical part that will take place in the classroom. Textbooks that cover the REA data modeling topic in-depth offer several chapters in this area. For example, Romney and Steinbart (2018) cover REA data modeling in almost four chapters (4, 17, 18 and 19). Therefore, using a traditional approach by covering complete chapter materials may not be practical nor possible. This paper solves this problem by providing all the required knowledge to create an accounting relational

DOI: 10.4018/978-1-7998-3473-1.ch075

database in one place. Furthermore, this paper provides a simplified example along each step to help to deploy the illustrated material.

FOCUS OF THE PAPER

This paper complements the Seow and Pan (2017) self-study online tutorial by providing a condensed version of the REA data modeling more from a theoretical perspective. It is designed to provide the basic knowledge required in each step in designing a relational database, accompanied by a simple example to show a possible outcome for that particular step. Furthermore, a clear methodology is provided on how to create a logical system design using a design approach that relies on business knowledge. This paper does not cover the remaining stages of the System Development Life Cycle (SDLC)¹. This paper can be used as a teaching aid for self-study material, a flipped classroom model or as supplementary material for an adopted textbook.

BACKGROUND

In this section, the basic required theoretical background for students to understand how to design a relational database using REA data modeling is provided. Furthermore, a simplified case study is being discussed along each step.

Preamble

Database design is the process of producing a detailed model of a database. This model contains all the needed parameters to generate a design in a data definition language, which can then be used to create a database at the beginning of its life cycle. The life cycle of any system, often called (SDLC), consists of the following stages:

- **System Analysis:** Represent collecting all the required information and defining the desired outcomes. This stage will produce a document generally known as System Requirements Analysis.
- **Logical design:** In this stage, a blueprint for the system is being created.
- **Physical design:** Translating the blueprint that was created in the previous stage into a software. This phase is also known as coding.
- **Implementation and Conversion:** In this stage, AIS will be deployed, and data will be transferred from the old system to the new system.
- **Operation and Maintenance:** The new system in this stage will be subject to routine testing and maintenance.

Database Design Approaches (Logical Design)

In logical database design, there are two different approaches. One approach is called Normalization, and this refers to the process of structuring data to minimize duplication and inconsistencies. It begins by storing all the data in one large table. After that, several rules will be used to split that large table into several interrelated and normalized tables as part of the database. The Normalization approach can be

similar to a paper writing style that starts by incorporating all the ideas and notes in one notebook; then, after that, the writer starts a refining process for the collection of notes to end up with a well-written and structured paper. The second approach is Semantic Data Modeling, in which the database designer uses business knowledge (technology) processes and information needs with respect to the semantic data modeling rules to create an efficient database. Using the writing analogy to illustrate this concept makes the semantic approach similar to when the writer starts by gathering all the required information and then placing such information in a well-defined paper structure and following a predefined plan (i.e., starts with the literature review, then define a problem, writing hypotheses ...etc.).

Semantic Database Design Using REA Modeling

The database design approach that this paper is following is a semantic approach called the REA framework that was designed by William McCarthy in 1982 (McCarthy 1982). In the spirit of the semantic approach design, the logical design that this paper illustrates follows these steps:

- **Acquire Business Knowledge:** This level covers the knowledge that must be acquired to identify the database users' needs and requirements. The semantic approach relies on the existence of such knowledge to create a well-designed database.
- **Design an REA diagram:** This is a diagram that provides an organization-wide view of the database and how the different elements interact with each other. One may think of the REA diagram as a general blueprint of a house, it gives the general layout of the house but does not provide specifics about each element (i.e., number of lights, outlets, trim specification in each room).
- **Internal level design:** In this level, using the REA diagram that was designed in the previous step, the database designer will create and describe the specifics of each data element. It is considered the lowest level of design and covers where and how data are stored, including the records layout, definition, and indexes. Using the above house blueprint analogy, the internal level design covers all house design specifics (i.e., number of lights, outlets, trim specification in each room).

In the following sections, the different steps in designing a database using a semantic approach that follows McCarthy's REA data modeling approach are described in more detail.

Acquire Business Knowledge (Step 1)

Using a semantic approach to design our database, the first step in the study will be acquiring business knowledge. This knowledge can be gained through the system analysis stage of the SDLC by utilizing different tools like questionnaires, surveys, interviews, and so forth. The quality of the information gathered could be affected by a data collection tool designer's overall industry knowledge and experience.

In this paper, a brief description of Green Goods Inc. sales operations is provided. The information provided may not be complete, and at a later stage, some assumptions need to be made by the users to complement the descriptions.

Case description ²

"Green Goods Inc. is a medium-sized company that sells small restaurant equipment. The sales representatives in Green Good Inc. receive customers' orders over the phone, or by email. After verifying the order information, the sales team creates a sales order and sends the information to the warehouse for

shipping. Also, they notify the accounting department to issue an invoice to customers. All invoices are due within 30 days; the company cashier will process any received payments and issue receipt voucher to the customer”.

REA diagram design (Step 2)

Data modeling is the process of defining a database, so it does represent all aspects of the organization, including its interaction with the external environment. This process happens during system analysis and conceptual design stages (Romney and Steinbart 2018). Data modeling can be executed through the **REA data model** that was specifically designed for AIS.

Generally speaking, the REA data model relies on identifying all the necessary information sources which we need to capture. Such information sources are called **Entities**. The REA data model target three types of entities, economic **Events** in each transaction cycle, the corresponding **Resources**, and the **Agents** who are participating in such events. The identified entities will be used in a modeling diagram called the REA diagram. To create an REA diagram, the below steps need to be followed:

Identify entities:

The REA data modeling focuses on the following three types of entities³:

- A. **Events:** Represent the events that the management would like to collect information about (i.e., purchase orders, sales, purchases, cash collection, etc.). There are two types of events: **economic events** that affect the company resources directly. They result from activities such as the sale of products to clients, receiving cash from customers. The second type of event is **commitment events**. This type does not affect resources directly but has other purposes, like planning and internal controls. A good example of this type is the purchase order; it does not decrease inventory directly, but it will provide a commitment for future purchases, which as a result, will decrease inventory. To identify events in any given case, one should assume that every event must be linked to at least another event. In other words, in each case, one should have at least two events. This assumption is withdrawn from the concept of “Economic Duality”, where a “give-get” relationship occurs. In typical business activities, a “give” event occurs when an organization must give up a resource to trigger a “get” event where they obtain another resource. For example, the event of a sale triggers a cash collection event or a purchase event triggers and linked to a cash payment event. Said that a database in a real-world scenario more likely will have more than two events.
- B. **Agents:** They are the individuals and departments that participate and support economic events. Agents can be both inside (internal agents) and outside the organization (external agents). Each event will be linked to at least two participating agents. For example, the event of a sale will be linked to a “Sales Representative” agent and “Customer” agent. Please keep in mind that there could be more than two agents linked to one event. Also, one agent may be participating in multiple events. For example, the “Customers” agent will participate in “Sales” and “Cash Collection” events.
- C. **Resources:** They are things of economic value to the organization and under its control. Resources are used in economic exchanges with trading partners are either increased or decreased by the exchange. Cash and inventory are examples of resources. To identify resources the recognized events are used to look for the resources that are linked to the events For example, if two events (Sales and Cash Collection) are identified, the user will be able to identify “Inventory” resource that is linked to “Sales”, and “Cash Accounts” resource that is linked to “Cash Collection” event. Each event will affect one resource with one exception to “Commitment Events,” which may not affect any resources directly. For example, “Sales Orders” is a commitment event that will not decrease

the “Inventory” resource directly but will lead to another event “Sales,” which, as a result, will reduce the “Inventory” resource.

Deploying the rules mentioned above on the Green Goods, Inc. case will generate the following entities presented in Table 1. Please note that the entities matrix was created by starting with Events followed by Agents and Resources.

Table 1. Entities list in Green Goods Inc. Case

Events “Each event will be linked at least to another event.”	Agents “Each event will be linked at least to two agents.”	Resources “Each event will be linked with one resource. Commitment events are an exception.”
Sales order	Sales Representative	Inventory (indirect impact)
	Customer	
Sales/Invoicing	Customer	Inventory (decreased)
	AR officer	
Cash collection	Customer	Cash Accounts (Increased)
	Cashier	

Creating a Preliminary REA diagram:

REA diagram describes the pattern for how the three types of entities should relate. As a matter of fact, the diagram name (REA) represents the diagram structure. Events will be placed in the middle of the diagram, while Resources and Agents will be on the sides, as shown in Figure (1).

Figure 1. REA diagram template

To create an REA diagram, one should:

- A. Place events in the middle of the diagram and list them in chronological order. In other words, we start with the oldest event and place it first, then follow it by the subsequent events. In the Green Goods, Inc. case, the first event will be Sales Order, followed by Sales and Cash Collection.
- B. Place the identified resources to the right (your left) of the related events. For example, one will place the “Inventory” resource beside the “Sales” event.
- C. Place the identified agents to the left (your right) of the related events. If an agent participates in two events, try to locate it to be close to both events. For example, “Customer” agents that participate in “Sales Order” and “Sales” events, is located to the left of the events and at equal distance from the events. If the agent participates in three events, you may create another symbol to avoid relationship overlaps.
- D. Connect the related entities using a straight line; the straight line represents a relationship.

These relationships described in step D can be one of the following types:

- **Economic duality (Give-Get) relationship** between events, where one event represents “Give” and the other represents the “Get”. For example, there is a relationship between “Sales” (Give event) and “Cash collection” (Get event).
- **The cause-effect relationship** between events. In this case, one event will cause or trigger the second event. This is very true for commitment events. For example, a “Sales order” event does not represent economic duality; nevertheless, it will cause the occurrence of a “Sales” event.
- **Stock flow relationships (inflow/outflow)**. This is a relationship that usually happens between events and resources. In this relationship, the event will either increase or decrease the related resource. For example, the “Sales” event will decrease the “Inventory” resource.
- **Accountability relationships**. This is a relationship that can be established between Events and Agents. Figure (2) shows the execution of this guideline on the Green Goods, Inc. case.

Figure 2. Step “D” in REA diagram development

Internal Level Design (Step 3)

As mentioned above, the REA diagram that was designed in the previous step will be used to create and describe the specifics of each data element. But before doing that, several concepts that are essential to this process are being explained below.

In database design, the focus is on **Entities**; they represent the point of interest and what the management would like to gather information about. After defining entities, one needs to identify each entity with its **Attributes** or characteristics that define the entity. All the data about the entity will be stored in a **Table**. Each row in that table represented one instance of that entity and called a **Record**.

Attributes are classified into three types. The first type is **Primary Key**, which is an attribute or combination of attributes that uniquely identify an item in a specific row. For example, a primary key for Green Goods inventory could be the “Item Number” or “SKU Number” attribute. The primary key is the first attribute that needs to be defined. The second type is **Foreign Key**; this key is an attribute that is a primary key in one table and used in other tables to execute a relationship. For example, the “Item Number” is a primary key in the “Inventory” table then used as a foreign key in the “Sales” table to identify the sold items. More discussion on this topic will take place in the following sections. Finally, **Non-Key** attributes are neither primary keys nor foreign keys; they are used to describe the entity and provide information that is essential for operations and/or reporting. For example, some non-key attributes for the “Inventory” entity are “Item Description,” “Item Location,” and the “MSRP.” For non-key attributes, a user must collect only enough information.

To create the internal design of a database, the following steps must be followed:

- 1- Create a table for each entity in the REA diagram.
- 2- Identify all the three types of attributes to each table.
- 3- Conduct completeness check

Create a table for each entity⁴

The ultimate goal of defining the entities of interest is to gather information about it; thus, one table will be created for each entity that was identified. For Green Goods, Inc. case and based on the REA diagram that was developed in Figure (2), nine (database) tables will be created, check Table 2 for further details.

Table 2. List of tables created in Green Goods

Tables / Attributes	Sales Order	Sales	Cash Collection	Inventory	Cash Acc.	Sales Rep.	Customers	AR officers	Cashiers
Primary Keys									
Foreign Keys									
Non-Keys									

Identify all the three types of attributes to each table.

As mentioned earlier, the **first type** of attributes that need to be defined is the primary key. A primary key is an attribute or combination of attributes that uniquely identify each incident of an entity; in other words, it can't be duplicated. Furthermore, one should keep in mind that the primary key cannot

be null (no value) for any incident. To choose a good primary key, the validation questions in Table 3 are recommended to avoid choosing the wrong attribute to represent the entity primary key.

The **second type** of attribute is foreign key, this key is an attribute that is a primary key in one table and used in other tables to execute a relationship. Foreign keys are created using the following rules. Please see **Different types of relationships** section to review the different types of relationships⁷.

- **The primary key of the first event will be used as a foreign key in the second event.** For example, “Invoice Number” as the primary key of the “Sales” event, will be used as a foreign key in the “Cash Collection” event. In this example, the foreign key will connect these entities and enable the database user to figure out which invoices are paid.
- The primary key of Agents will be used as a foreign key in the related Events.** For example, “Customer Number” as the primary key of the “Customers” agent is used as a foreign key in the “Sales” event.
- The primary key of Resources will be used as a foreign key in the related Events.** For example, “Item number” as the primary key of the “Inventory” resource is used as a foreign key in the “Sales” event.

Table 3. Primary key validation questions⁵

Question	Optimal answer
Does the proposed attribute differentiate one entity incident from another?	Yes
Is it possible for any duplicate attribute values?	No
Is it possible for the proposed attribute to have no value?	No

The **third type** is Non-key attributes, they are neither primary nor foreign keys. All Non-key attributes in a given table must describe the characteristics of the entity. For example, in the “Sales” event

Table 4. Database design checklist

#	Element	Verification
1	Number of entities	- At least two events. - At least two agents for each event. - At least one resource for each event with the exception of commitment events.
2	Number of tables	- At least one table for each entity we identified.
3	Primary keys	- One valid primary key for each table (see Table 3)
4	Foreign keys	- Each relationship will require a foreign key. In other words, if we have nine relationships, we should have nine foreign keys. - Generally speaking, all the foreign keys will be located in the “Events” tables; please check Table 4 as an example.
5	Non-Key attributes	- All non-key attributes must describe the entity that we are examining. - Tables that represent events (Transaction Tables) tend to use a non-key attribute that changes with every transaction (i.e., Sold quantity attribute in Sales table). While tables that represent agents and resources (Master Tables) tend to include a non-key attribute that does not change that often (i.e., MSRP in the inventory table).

Table 5. List of tables created in Green Goods and all the attributes

Tables / Attributes	Sales Order	Sales	Cash Collection	Inventory	Cash Acc.	Sales Rep.	Customers	AR officers	Cashiers
Step 1: Identify Primary Key(s)	-SR No.	- Invoice No	- Receipt No.	- SKU number	- Acc. No.	- Rep ID.	- Customer ID	-AR ID	- Cashier ID
Step 2: Foreign Keys	-SKU number -Rep ID -Customer ID	-SKU number* -Customer ID* -AR ID - SR No.	- Acc. No. -Customer ID* - Cashier ID - Invoice No.	N/A	N/A	N/A	N/A	N/A	N/A
Step 3: Non-Keys	- SR Date - SR Qt.	- Invoice Date - Qt. sold. - Unit price **	- Receipt date - Receipt amount. - RV notes.	- Item description. - MSRP - Warranty period.	- Account location. - Account Currency	- Rep Name. - Commission Rate	- Customer Name. - Enrolling date. - Shipping Address. - Billing address	- AR Name.	-Cashier Name

table, “Invoice Date” is a non-key attribute that describes the sales transaction. There are no specific requirements for defining Non-key attributes other than collecting all the information that is needed to describe the entity to fulfill any operation and/or reporting requirements.

Conduct a completeness check

In verifying the completeness of the logical database design, it is recommended to use the following checklist:

Cardinalities

Cardinalities define the nature of relationships between two entities by indicating how many instances of one entity can be linked to each instance in another entity (Romney and Steinbart 2018). The nature of the relationship between entities is defined by the norm followed (business logic) or a specific policy adopted by the organization. For example, cardinalities define how many invoices (instances of sales) can be linked to one receipt voucher (instance of cash collection): Issue one receipt voucher for each paid invoice? Or Issue one receipt for multiple paid invoices?

Defining cardinalities is usually done before creating tables; cardinalities may result in a specific type of relationship that will require creating new tables. Due to the potential complexity of this topic, it was elected to delay discussing cardinalities until a basic understanding of databases, the structure of tables is being established, and it also helps to realize the important role of foreign keys in representing relationships.

Cardinalities are used to represent the specifics of how entities are reacting with each other in the REA diagram. More specifically, how many instances of one entity can be linked to another entity? Thus, in any given relationship, two directions of relationship will be discussed. As explained in Figure (3), the first direction illustrates how many instances of Entity A could be linked to one instance of Entity B, while the second direction shows how many instances of Entity B could be linked to Entity A.

In each relationship direction, two values will be defined as one pair of cardinalities; the first is a **Minimum Cardinality** that represents the minimum number of times that the first entity must be linked to the second entity. The second value is a **Maximum Cardinality** that represents the maximum number

of times that the first entity could be linked to the second entity. Accordingly, each relationship will generate two pairs of cardinalities to represent both directions, as shown in Figure (3).

Figure 3. Pair Cardinalities in a relationship

Representing cardinalities for each direction can be done in different notation formats (symbols, numeric, etc.). In this paper, a numeric notation system will be used; this system can be found easier to explain and make more sense to accounting students. Using the numeric notation system will result in two possible values of Zero and One for a minimum cardinality, while the maximum cardinality has two possible values of One and Many. Table 6 shows a summary of the possible cardinalities' values and their symbols.

Table 6. Possible values for cardinalities

Cardinality type	Possible Values	Number/Symbol used
Minimum (The minimum number of times that the first entity must be linked to the second entity)	Zero	0
	One	1
Maximum (The maximum number of times that the first entity could be linked to the second entity)	One	1
	Many	"M" symbol is used. If two "Many" cardinalities exist in one relationship, the second cardinality will use the "N" symbol.

Cardinalities Interpretation and Implementation

In this section, cardinalities are explained. Followed with a proposed methodology to help to translate policies to cardinalities. The basics of cardinalities interpretation rely on understanding what each cardinality represents. The minimum cardinality basic interpretation reads

Each (*One instance of Entity A*) must be linked at least to (*enter the value of the minimum cardinality*) in (*the second entity instances*).

While the maximum cardinality basic interpretation will be

Each (*One instance of Entity A*) can be linked at most to (*enter the value of the minimum cardinality*) in (*the second entity instances*).

As an example, if the pair of cardinalities that represent the relationship between inventory and sales has a value of (0, M), the cardinalities interpretation structure will result in:

- Minimum cardinality (0): Each Inventory item must be linked at least to Zero invoices.
- Maximum cardinality (M): Each inventory item can be linked at most to Many invoices.

It worth noting “Inventory Item” was used as a representative of one instance of the “Inventory entity, while “Invoices” was used as a representative of the “Sales” entity multiple instances. The reader should keep in mind that cardinalities interpretation relies on the understanding of the business environment. Acquiring enough business knowledge is important to provide meaningful interpretation for any of the given cardinalities. Thus, the above basic interpretation can be transformed into the following statement.

“Each inventory item can be sold an unlimited number of times, but there may not any sell for a while.”

This statement does reflect normal business logic; no one knows if any inventory item the company acquired will ever sell (Minimum = zero), and, in a normal situation, one will sell the item several (Maximum = Many) times over the course of our inventory economic life.

Another example is the pair of cardinalities that have a value of (0, M) between the Sales entity and the Cash Collection entity.

The cardinalities basic interpretation for this pair of cardinalities is:

- Minimum cardinality (0): Each invoice must be linked at least to Zero cash collection receipt vouchers.
- Maximum cardinality (M): Each invoice can be linked at most to Many cash collection receipt vouchers.

The minimum cardinality indicates that each invoice created may not have any cash collection receipt vouchers linked to it. Using some basic understanding of business knowledge, it can be concluded that the minimum cardinality (Value of 0) implies no down payment will be required when upon selling. When examining the maximum cardinality (Value of M), it can be concluded that the company accepts multiple payments for each invoice; this is an indication of installment sales. Combining the two cardinalities in one statement will result in the following interpretation:

The company sales policy is installment sales with zero down payment

This is a company-specific policy. Other companies may have different requirements. For example:

- Cash only.
- Installment with a down payment.
- On account, but paid in full.

Now, after explaining how to read cardinalities, it is needed to explain how to translate any given policy to a pair of cardinalities. To do that, the following methodology is suggested:

1. Identify the pair of entities affected by this policy. In other words, which relationship in the REA diagram are being examined.
2. Identify the direction of the relationship. As explained earlier, each relationship has two pairs of cardinalities, and each pair represents one direction. Please check Figure (3).
3. Based on business knowledge, answer the following questions to define the minimum and maximum cardinalities.

Table 7. Cardinalities example for Green Goods, Inc.

Steps	
1- Identify the pair of entities affected by this policy. In other words, which relationship in your REA diagram you are examining?	We have two apparent entities: - Sales Orders - Sales Representatives
2- Identify the direction of the relationship.	We have two directions: - Sales Representatives to Sales Orders. - Sales Orders to Sales Representatives.
3 – Answer the following questions A- At least, how many times one instance of entity A must be linked to Entity B table? B- At most, how many times did one instance of Entity A have to be linked to the Entity B table? Min. Cardinalities has two options - Zero. - One. Max. Cardinalities have two options - One. - Many	<u>Sales Representatives to Sales Orders:</u> A – At least, how many times did one sales representative have to be linked to sales orders? Zero times; sales representatives spend three months in training and may not generate any sales orders during that period. B- At most, how many times did one sales representative have to be linked to sales orders? Many times; this is business logic, you hire the sales representatives to sell several times and not only one time. Pair of cardinalities for this direction is (0, M) <u>Sales Orders to Sales Representatives</u> A- At least, how many times one sales order must be linked to a sales representative? One time, the company policy states that each sales order must have one sales order. B- At least, how many times one sales order must be linked to a sales representative? Many times, the company allows for more than one sales representative to work on the same sales order. Pair of cardinalities for this direction is (1, N)

- A. At least, how many times one instance of Entity A must be linked to the Entity B table?
B. At most, how many times one instance of Entity A must be linked to the Entity B table?

This methodology relies on thin slicing any given policy to ease the process of identifying cardinalities in any given relationship. To illustrate this methodology, the following description to the Green Goods case is being added:

“Greens Goods hires sales representatives to market for the equipment that they sell. Sales representatives usually will generate sales orders after 3 months of a mentoring period. Green Goods sales orders only get generated through sales representatives. If any customer contacts the company directly, the customer will be referred to as one of the current sales representatives. In some cases, the company does allow more than one sales representative to work on the same sales order.”

Please check Table 7 for the solution to this case.

Different Types of Relationships

Identifying the pair of cardinalities in each relationship in an REA diagram will result in different types of relationships. Three basic types of relationships between entities are possible, depending on the maximum cardinalities in any given relationship (Romney and Steinbart 2018).

- 1- One-to-One relationship: Both of the maximum cardinalities in the relationship has a value of 1.
- 2- One-to-Many relationship: One maximum cardinality has a value of 1 while the other is Many. The order of values is irrelevant.

- 3- Many-to-Many relationship: Both of the maximum cardinalities values in a relationship have a value of “Many”.

Defining the different relationships in any database design is important. The first two types of relationships will not alter the database design that was created earlier in this paper. This is not the case for the third type, Many-to-Many relationships.

Many-to-Many relationships cannot be executed in databases, as a result, it is required to break them into two One-to-Many relationships by using a new third entity that is called a “Join Entity.” The primary key of the join entity table will be consistent with the primary key of the two entities that we are examining. Table 8 illustrates the join table concept between “Sales Rep” and “Sales Orders” Many-to-Many relationships.

Table 8. Join table between “Sales Rep.” and “Sales Orders”

Tables / Attributes	Sales Order	SalesOrder_Sales Rep (Join Table)	Sales Rep.
Step 1: Identify Primary Key(s)	-SR No.	- SR No. - Rep ID.	- Rep ID.
Step 2: Foreign Keys	-SKU number -Customer ID		N/A
Step 3: Non-Keys	- SR Date - SR Qt.		- Rep Name. - Commission Rate

SOLUTIONS AND RECOMMENDATIONS

The REA design process is hands-on and helps the students to:

- Understand the basics of SDLC.
- Differentiate between normalization and semantic database approaches.
- Create an REA diagram using REA data modeling.
- Ability to create an internal level design (Tables) using an REA diagram.
- Understand cardinalities and how they affect database design.

FUTURE RESEARCH DIRECTIONS

Entity Relationship or Enhanced-Entity-Relationship (EER) modeling is the de facto standard for relational database design in the broader field of Information Systems. The database design in AIS is considered to be a special case. However, it would be interesting to compare and contrast the REA modeling approach to database design in AIS over EER modeling. In our future works, we also intend to address this issue.

CONCLUSION

It is expected that the examples and the descriptions in the paper will complement the Seow and Pan (2017) self-study online tutorial and ease the burden both on the instructors and the students in designing a relational database. Contrary to traditional books that cover this topic using multiple chapters, this paper provides a comprehensive resource to design relational databases in accounting. This has been achieved by providing concise and simplified step by step guideline that covers the basic knowledge required in designing a relational database in AIS. Furthermore, this paper provides a simplified example along each step to help to deploy the illustrated material. Finally, we provided notes to instructors that cover possible discussion points with students, validation points, and any justification for a methodology we used in this paper. We believe this paper will help students to acquire all the required basic knowledge to create a relational database in a short period of time, which is becoming more and more important given the pressure to cover multiple topics in AIS courses to meet the market demand.

KEY TERMS AND DEFINITIONS

Agents: A type of entity that represents individuals who participate and support the economic event.

Attributes: Characteristics that define the entity

Cardinalities: Graphical or numerical expression that define the nature of relationships between two entities by indicating how many instances of one entity can be linked to each instance in another entity.

Entities: A concept that represents the point of interest of what management would like to gather information about.

Events: A type of entity that represents an activity of interest.

Foreign Key: This key is an attribute that is a primary key in one table and used in other tables to execute a relationship.

Logical Design: Methodology of describing how information flows in a system regardless of which medium is actually used.

Primary Key: An attribute or combination of attributes that uniquely identify an item in a specific row.

REA Data Modeling: Methodology used to design databases in Accounting, it starts by defining the different types of entities then, using business knowledge, organize the relationship between these entities.

Resources: A type of entity that represents things of economic value to the organization and under its control.

Semantic Approach: Using business knowledge to create a database.

System Development Life Cycle (SDLC): A process that describes a system life cycle, this cycle starts with system analysis, conceptual design, physical design, implementation, and conversion and ending with operation and maintenance.

ENDNOTES

¹ Note to instructor: Please keep in mind that the above description of SDLC is a very brief illustration of what each stage entails. One can explain to the students that each stage will have more activities (i.e., feasibility studies, alternative analysis evaluation, etc.).

² Note to instructor: Providing a limited amount of information at this stage is intentional; it is designed to improve the students' analytical skills by asking them to be critical of the provided information and facilitate discussion.

- ³ Note to instructors: It will be beneficial to conduct a discussion about which entity should be identified first. The students will conclude that Events are the first type of entities that needs to be identified, followed by agents and resources. Students frequently ask about the inventory availability in the online sale environment and when a database system should update the available inventory. Does it happen after the customer place item in the cart or after they place actual order with valid payment? What are the pros and cons of each approach?
- ⁴ Note to instructors: One can ask the students to use the validation questions in the following problems: Is the “Invoice number” a good primary key for the “Sales” entity in Green Goods? Green Goods invoicing system uses a serial number for invoices that:
A-Alphanumeric invoice sequence (YYYY-Serial number), i.e., 2018-0001.
B-Simple serial number that we reset at the beginning of each year, i.e., 00001
- ⁵ Note to instructors: This is a good opportunity to remind students of the importance of obtaining sufficient business knowledge in database design using REA data modeling.

Embodied Conversation: A Personalized Conversational HCI Interface for Ambient Intelligence

INTRODUCTION

Ambient Intelligence (AmI) and Smart Environments (SmE) are built on three foundations: Ubiquitous computing, ubiquitous communication, and personalized adaptive interfaces. One of the key requirements is the fact that interaction takes place through natural interfaces, in such a way that people can perceive the presence of smart objects and machines as little as possible, and only when the system cannot achieve its functionality without intervening for the user's attention. Namely, the use of physical, especially non-freeform, controllers (e.g. touch-screen, remote, mouse, keyboard) hinders natural interface and establishes a strong barrier between the user and computer. Moreover, speech and body language are part of the input/output Human-Computer Interface (HCI) modalities, which have the benefit of being a natural modality for communication between humans. The speech as input modality can be used in many scenarios, which are also reflected in the complexity of the automatic speech recognition system. Humans are social beings, who utilize all available signals, from linguistics, language, and speech, to paralinguistic and non-verbal in the perception, understanding, and production of information in face-to-face communication. Some of the paralinguistic and non-verbal audio events can be processed in parallel with the automatic speech recognition system, with the possibility to share some modules, such as feature extraction.

DOI: 10.4018/978-1-7998-3473-1.ch076

Aggregation in (multimodal) understanding and use of natural language is especially supported through concepts of Conversational Interfaces (CIs) and Embodied Conversational Agents (ECA). In recent years, the CIs have become an important research and development topic in academia and the ICT industry. Smart environments utilize Artificial Intelligence (AI) increasingly and incorporate smart objects, such as: Devices, wearables, virtual agents, social robots, etc. Leading companies (e.g. Google, Amazon, Microsoft, Apple) have been making huge investments in the development of supporting technologies of Artificial Intelligence, such as Deep Learning and Natural Language Processing (NLP). The aim of these ventures is to create systems that will enable users of smart systems to obtain information and access services in a more natural, embodied conversational way. The classical vision of CIs incorporates dialog systems, and voice-enabled interfaces supported by Natural Language Processing. The multimodal vision of CIs, however, also aggregates embodiment and embodied cognition (as part of embodied language processing) in input (gesture-enabled user interfaces) and output (embodied conversational agents). Namely, CIs with virtual ECA capable of understanding verbal and non-verbal signals and capable of generating them, can engage with a human user on a more personal level. Particularly, through more conversation-like flow of the interaction, these Embodied Conversational Agents (supported by Natural Language Processing (NLP) and Embodied Language Processing (ELP)), may deliver new interaction models capable of adapting to the user's context and facilitating context of the conversational situation not only via modalities like speech, but also through visual interpretation and representation of information and social cues.

Despite all investment in this research area, an important amount of challenges still need to be solved. One barrier, which is connected with the users' desire to communicate in their native language, has to deal with the language questions. The languages outside the economic interest of leading companies are usually under-resourced, which presents an additional challenge for the intelligent ambient development process. A solution applied in the last few years is oriented toward collecting open and freely available language resources. In the case of such resources, some modalities, such as text, are available more frequently than others, as is speech combined with transcriptions. The availability of language resources is, thus, one of the key questions in the era of industry digitalization.

The intelligent ambient, and especially its manifestation in the form of the Embodied Conversational Agent, plays a crucial role in many areas of modern society. The application areas can range from general use in a smart home, to a dedicated use in a highly specialized e-Health environment. The common goal is to ease the user's interaction, with the objective to make it as natural as possible.

The background and literature review are presented first. The novel Ambient Intelligence embodied conversational model for HCI is proposed and the main modules, which are necessary to establish a natural communication, are described. The objective is to improve the quality of HCI in Ambient Intelligence, with the usage of advanced approaches. In addition, the services based on the proposed interaction model are presented. The chapter concludes with future research directions.

BACKGROUND AND LITERATURE REVIEW

A general overview of speech as the input modality is given in (Rabiner et al., 1993), where the authors addressed all different entities of an automatic speech recognition system. For more than two decades, Hidden Markov Models were used as basic acoustic models (Huang et al., 2010; Bilmes 2006) for different speech recognition scenarios that were applied in the research and industrial domains. Important progress was made in the area of robust speech processing, where noise reduction techniques and speech

enhancement algorithms were improved (Anusuya et al., 2011). The most advanced robust feature extraction techniques can enable the usage of spoken input in harsh conditions (Bagchi et al., 2015), but there are still many other factors which influence the performance of a speech recognition system (Benzeghiba et al., 2007).

The development of Graphical Processing Units with multiple cores and a large number of spoken language resources led to the success of various Deep Learning architectures (Zhang 2012). As a result, speech recognition accuracy improved for those languages where sufficient training material was available, but the group of under-resourced languages still presents a challenge for the research community (Besacier et al., 2014). When languages with complex characteristics (i.e. agglutinative, tonal, highly-inflected, free word order) are combined with spontaneous speech (Benzeghiba et al., 2007), which is frequently present in intelligent ambient, the speech recognition accuracy still decreases. These language issues also open the need to include linguistic knowledge, particularly in the domain of discourse (Verdonik 2015). The authors in (Christensen et al., 2015) and (Vacher et al., 2015), show that usage of advanced speech recognition techniques for communication in intelligent ambient can be beneficial for end users, as it eases the communication with the system and improves the naturalness of communication. An additional aspect that can be incorporated in spoken input modality is machine translation (Anastasiou 2015). Its role is to support the usage of intelligent ambient by foreign speakers, which can be a benefit in the case of a public environment (e.g. museums, exhibitions, transportation hubs...).

In addition, natural and multimodal co-verbal behavior is becoming one of the key methods of how machine responses should be represented to the users (Luger et al., 2016; Venkatesh et al., 2018), where the behavior is manifested through the Conversational Interfaces (CIs) and Conversational Agents (CAs). The idea behind CAs and CIs is that people could interact with (or speak to) smart objects, such as smartphones, social robots, and other gadgets, in more natural way in order to issue commands, or to engage in chats, etc. The CAs already serve in many different roles and within several Conversational Interfaces, such as: Tutors, guides, trainers and actors. The rise of personal assistants like Amazon Alexa, Cortana, and Siri, and other chat platforms with social bots, like Facebook Messenger and Google Allo, had also made accommodation to the CAs possible to the wider public. Thus, CAs have, become an indispensable tool in everyday scenarios (Graesser et al., 2017; Ciechanowski et al., 2018), where chatbots and 2D cartoon-like representations of talking heads are a good example of the facilitation of implementation consumer-oriented state-of-the-art AI that already simulates some aspects of human behavior (Firth, 2017; Kuhnke & Ostermann, 2017; Ochs et al., 2017). Nevertheless, chatbots are those type of CIs with no explicit goal other than engaging the other party in an interesting or enjoyable conversation (Hill et al., 2015; Fryer et al., 2017; Levesque, 2017). Therefore, in order to simplify understanding and tasks further, the CAs must also incorporate cognitive artefacts of conversation, through which the information (goal) is presented through a flexible representational medium that enables activation of communication channels, such as are utilized in face-to-face interaction. Embodied Conversational Agents (ECAs) are, therefore, developed for advanced HCI, that are capable of interacting with humans in face-to-face situations. These agents interact through utilization of chat (speech) and their articulated body placed in virtual worlds. Namely, in the field of Face-to-Face Conversation, it has been shown that the most natural way to interact is to visualize and emulate communication through synchronized verbal and co-verbal cues (Kacprzyk & Zadrozny, 2010). Therefore, the ECAs are showing potential, especially in scientific circles, and are on the verge of their integration within various conversational concepts and interfaces, including tutors, guides, trainers and actors (Veletsianos & Russell, 2014; Garrido et al., 2016; Kim & Baylor, 2016; Klopfenstein et al., 2017). In this way, ECAs represent a highly suitable concept for machine-based presentation of information. Nevertheless, the primary goal of an ECA, to

give an artificial entity the capacity to engage with the user in the form of a human-like conversation, nowadays, still represents an important research challenge, where face-to-face interaction itself is much more than just a speech accompanied by the repetitive movements of limbs and face, while interaction entails multiple variations that are correlated in dynamic and highly unpredictable settings and under dynamical and rapid changes (Kopp & Bergmann, 2017; Porcheron et al., 2017). Additionally, humans tend to incorporate social and interpersonal signals into multimodal responses, in order to ‘color’ the final outcome (Pelachaud, 2015; Porcheron et al., 2017; Krämer et al., 2018).

PERSONALIZED CONVERSATIONAL HUMAN-COMPUTER INTERFACE

In this encyclopedia article, a novel embodied conversational model applied to Ambient Intelligence is proposed. The core of the conversational model is Embodied Conversational Agent EVA, capable of capturing and processing multimodal input signals (e.g. Automatic Speech Recognition, gesture recognition), and of generating appropriate multimodal output signals in the form of synchronized verbal and co-verbal behavior. This architecture provides advanced solutions compared to methods presented in the literature review, with the objective of improving the natural way of HCI.

Human Spoken Interaction and Automatic Speech Recognition

Automatic Speech Recognition (ASR), as one of the multimodal inputs, is one of the already traditional solutions of how to capture the user’s uttered intention and prepare the information for further processing in the NLP chain in the form of text. A typical Automatic Speech Recognition system has to deal with the uttered information on two levels, where the first one addresses the acoustic characteristics of speech, and the second one considers the language characteristics of speech. A general Automatic Speech Recognition system has the following building blocks:

- Audio input,
- Robust feature extraction
- ASR decoder,
- Acoustic models,
- Language model,
- Grapheme to phoneme conversion,
- Text output.

The spoken audio signal can be captured with various types of microphones, from single-channel closed talking microphones, which can also be part of user terminal equipment, such as a smartphone, to multi-channel microphone arrays, as they can be found in a typical intelligent ambient solution. The quality of the capturing device plays a very important role in practical solutions, as its role is crucial for the overall accuracy of the system. Sometimes, a dedicated push-to-talk system can be applied to isolate the uttered speech better. The acquired speech signal is then preprocessed, with the goal to improve the signal and increase the robustness of Automatic Speech Recognition against noise and other background audio sources (e.g. music, other conversations), which are frequently present in intelligent ambient. In the next step, feature vectors are extracted from the speech signal, which represent the key characteristics of the uttered sentence. Different types of feature extraction algorithms can be used, which depends on

consecutive speech recognition steps. Two of the very frequently applied feature extraction algorithms are Mel-Frequency Cepstral Coefficients (MFCC) and Filter Bank Cepstral Coefficients (FBCC).

The objective of acoustic models is to represent the phonetic and acoustic characteristics of the human speech signal. Several different approaches were used in the past for completing the acoustic modeling task. The first widely deployable Automatic Speech Recognition systems for intelligent ambient were based on Hidden Markov Models. The Big Data perspective also influenced the ASR area. With the availability of various media and user-generated content (news shows, TED talks, audio books, parliamentary debates, conversations), the amount of data needed for acoustic models increased dramatically. In parallel, Graphic Processing Units (GPU) with a large number of cores become widely available. As a consequence, different Deep Learning approaches, like those based on Deep Neural Networks (DNN), were introduced to the area of Automatic Speech Recognition, with the result of improving the speech recognition accuracy and robustness. General acoustic models are speaker independent, but, according to the context and user scenarios, speaker adaptation can also be applied, to increase the speech recognition accuracy further. One of the methods used frequently to carry such speaker adaptation in intelligent ambient is iVectors. The main focus of language models is to represent the characteristics of text, encoded in the speech signal. One of the general approaches is to represent text in the form of n-grams, and then apply Artificial Intelligence approaches, such as Deep Learning, to model them. The grapheme-to-phoneme module is responsible for linking the acoustic and textual dimension. The general approach is to use manually produced phonetic vocabularies, but also automatic approaches carrying out on-line grapheme-to-phoneme conversion with the support of machine learning can be applied in intelligent ambient. In this case, support for new words and domains can be added. The Automatic Speech Recognition decoder is the main entity, which then combines the gathered knowledge from all three sources and estimates the best output results. The decoding phase can be performed in a single step, or in multiple steps, where results of previous phases are used to improve the end result. This approach is also applied in the case where different types of systems (e.g. DNN, CNN, HMM) are combined to produce improved speech recognition results.

In the intelligent ambient, various spoken scenarios can occur during the communication. The basic one is supporting only isolated or connected speech with limited pre-defined grammars. Such basic scenario has limited applicability in intelligent ambient, mainly for control and command scenarios, but it can prove robust speech recognition accuracy even in acoustically degraded environments. A more advanced scenario supports large vocabulary continuous speech, where the user utters sentences in a read or planned way. Such a system can be used to process different media or user-generated content, which can play an important role in the case of intelligent ambient, as a source of additional information for activity prediction. The most complex scenario is spontaneous speech recognition, which covers the human communication entirely, and provides successor modules access to the complete information uttered. With the increasing complexity of scenarios, the speech recognition system complexity also increases, which can present a challenge for intelligent ambient architecture.

One of the important aspects of Automatic Speech Recognition in intelligent ambient is the question, where is the computation taking place. The presented methods from the area of Digital Signal Processing and Artificial Intelligence need a high amount of computing power. In the case of mobile applications, virtual assistants and other similar ICT services, the Automatic Speech Recognition is carried out in the cloud or edge. User analyses have shown that an important portion of humans feel dissatisfied with the concept of transmitting their voice recordings to the cloud for processing. As a result, Automatic Speech Recognition approaches, which require low-power equipment, are gathering in importance for intelligent ambient.

An important aspect of Automatic Speech Recognition is also the question of language support. A prerequisite for developing Automatic Speech Recognition systems is the availability of large amounts of spoken language material, which needs to be entirely partly annotated, and/or transcribed by humans. An additional challenge is presented by language characteristics, as some of the languages (e.g. tonal, highly-inflected, agglutinative) are more complex from the Automatic Speech Recognition point of view than others. Currently, the commercial speech recognition systems are available for approx. 100 languages, where the commercial interest is present. In the case of other, under-resourced languages, approaches such as cross-lingual speech recognition can be applied, but the achieved results are usually applicable only for simple tasks.

In the case of Human-Computer Interaction in intelligent ambient, the uttered speech is not the only feasible information source which can be used beneficially for acquiring knowledge about the user and his activities. Additional information can be collected from paralinguistic and non-verbal audio events, such as breathing sounds, a laugh, snoring, eating-sounds... Other important information, which can be extracted from the captured audio, is dealing with the speaker's emotions and stress level. Both of them can be used further by an Embodied Conversational Agent, to be able to personalize the response to the user's verbal interaction better.

Image Recognition and Human Gestures

A crucial part of every human-machine interaction is mutual understanding. When dealing with gesture conversation, communication participants deal with visual information. Image recognition is a process of identifying objects, people and actions in images in the video stream, where a camera gathers the multimodal input visual information. This information is then processed by machine vision algorithms and Artificial Intelligence software. While human and animal brains recognize an object in an image with ease, this is still a difficult job for Artificial Intelligence. Namely, nowadays, computers, to solve such tasks, are trained with supervised learning techniques on large sets of annotated images. The best performing algorithms include convolutional neural networks, like SSD (Liu et al., 2016) to recognize objects in the video in real-time. In this case, in the first part of the network, convolutional layers are used to extract characteristic features of each object class, in the second part fully connected layers are used to classify extracted features into specified classes. When dealing with video, the temporal dimension is added to individual images, while sequential images are processed one by one. For recognized objects, object tracking algorithms are used to define gestures' trajectory, where, in the case of gesture recognition, image recognition algorithms have to distinguish between specific objects present in the intelligent ambient. Additionally, they need to segment the image into arms' parts in order to process their movement.

Multi-Modal Aspects of Communication in Intelligent Ambient

Embodied behavior (gesticulation), and being able to express information beyond words and even speech, is taking a significant role in human-machine interaction as a key method of how machine responses are represented to the users. Namely, in natural face-face interaction, the co-verbal signals conveyed together with spoken content, or even in the absence of it, are essential for establishing discourse cohesion. One could say that the verbal/linguistic parts of spoken language (e.g., words, grammar, syntax) carry symbolic/semantic interpretation of the message, while the co-verbal parts (e.g. gestures, expressions, prosody) carry the social component of each message, and serve as an orchestrator of communication.

Thus, co-verbal signals differentiate from general motor actions by representing what is articulated and recognized (e.g. scratching while thinking or waving goodbye), rather than simply expressing something through a different transducer (e.g. screen wipe). Overall, the co-verbal signals in machine responses actually enable users to react to these responses socially; more specifically, users start to exhibit social behaviors that are similar to those observed when engaged in interpersonal communication. However, aligned with the uncanny valley phenomenon (Mori, 1970), the more human-like the machine response, the greater the expectation and, more intense, the negative affect it causes, when dissynchrony occurs (e.g. less natural voice, flickers in animation, wrong gestures/expressions, non-synchronized power of co-verbal expressions, etc.) (Poria et al., 2017; Ciechanowski et al., 2018). The major source of possible discohension (negative perception) in the response is the lack of ‘conversational knowledge’. Such knowledge consists of communicative signals from linguistic, paralinguistic, and even social domains (Figure 1). Moreover, in contrast to language, there are no universal rules (e.g. grammar) that would create a finite set of causes and predict effects. In order to represent viable human-like responses, these signals must be fused into real human like responses, and various knowledge sources are required. As outlined in Figure 1, we propose to design a complex function f , which utilizes information fusion in order to combine Natural Language Processing (NLP) and Embodied Language Processing (ELP) into Embodied Language Understanding (ELU).

Figure 1. Multimodal fusion model of Embodied Language Understanding

The proposed model outlined in Figure 1 is built around the concept that a ‘multichannel’ representation of an idea via audio and visual signals, e.g. fusion function $\mathcal{F}$. It is first formulated on a cognitive level through symbolic fusion ($\mathcal{F}^S$), and on a representational level through fusion of form ($\mathcal{F}^F$). The global symbolic level fusion function is defined as

$$\mathcal{F}^S = f(L, P, S) \quad (1)$$

It establishes an overall symbolic link among various signals, which are represented in various domains of cognitive linguistics, such as pure linguistics L , para-linguistics P , and social context S . The nature of fusion function f and correlation of various individual signals and their individual contribution is, in many cases, already well described via the modern theories in cognitive linguistics and communicative behavior. However, we cannot simply ‘glue’ the narrower knowledge into a common strategy. Hence, we envisage that all conversational theories are relevant, and contribute to the ‘cohesive’ generation of human co-verbal behavior. Thus, any individual contributions must be observed under a common context, and any generated knowledge must reflect this complexity, induced due to convergence of signals. The nature of representational level fusion function is best described as

$$\mathcal{F}^G = g(\mathcal{F}^S, I, GS, t) \quad (2)$$

where g represents the fusion function for defining the physical nature of the ‘multichannel’ representation of the idea, with a clear reference to actual physical preferences. Thus, Equation 2 not only denotes the shape of expressions, but also the propagation of how the shapes are formed (e.g. movement phases, fluidity, power) in relation to the formulation of verbal counterparts (e.g. local pitches, prosody, and prosodic phrases). In the next chapter, we outline an example of the utilization of the proposed model, and omni-comprehensive expressive spoken dialog systems incorporating an Embodied Conversational Agent as an active participant.

Spoken Dialog System with Multi-Modal Functionalities

The final step in interaction is to react to the multimodal input in a human-like fashion. Thus, to generate a machine response incorporating an ECA, which can speak through voice and body (e.g. in the form of speech synchronized with embodied conversational behavior). This is usually achieved through a Spoken Dialog System (SDS) (Figure 2), enhanced with Automatic Speech Recognition (ASR) and Gesture Recognition (GR), which are observed as two primary input modalities. The expressive Embodied Conversational Agent delivering conversational responses is observed as the primary output modality. In between is an application driven, and task-oriented Dialog Manager (DM), used to understand conversational signals by facilitating multimodal sensing.

In the proposed HCI, the central component responsible for generating human-like conversational responses, e.g. the Natural Language Generator (NLG), is the expressive Text-To-Speech synthesis system (eTTS) called PLATOS. PLATOS is designed based on the EVA behavior generation model (Rojc et al., 2017), a practical implementation of the outlined multimodal fusion model (ELU in Figure 2). The EVA behavior generation model comprises of a Text-To-Speech synthesis processing que which is interlinked with the processing que responsible for planning and modeling of conversational behavior.

The EVA behavior generation engine converts context supplied by the DM (e.g. text to be spoken, domain and additional social cues) into speech accompanied by human-like synchronized gesticulation and lip movement. In general, sentences/statements can have multiple interpretations in various contexts, therefore, the interpretations of the communicative intent can overlap partly or fully, and introduce ambiguities and several inconsistencies. Thus, during the *Classification of the intent*, the Semiotic Grammar is used for classifying individual semantic and morpho-syntactic sequences in the text onto correspond-

Figure 2. Omni-comprehensive spoken dialog system capable of responding in a human-like conversational manner

ing parametric descriptions of the semiotic class (subclass) given the classified social cues (situation, dialog function and role, etc.). In the *Planning of the intent phase*, the inconsistencies and ambiguities are resolved by using integration, elimination, and selection. In order to do this, the prosodic information (prominence, stress, prosodic phrases), predicted by the TTS modules, is used in combination with further social cues (e.g. person, gender and emotion). In the *Planning of the Movement phase*, a movement model is generated which represents an animated sequence of shapes/poses that, together, represent the targeted visual part of conversational signals. For each model at least, a stroke movement phase must be defined, and aligned with the acoustic prosody information, as specified by the TTS engine. Finally, in the *Synchronization of the shape phase*, the planned models, which are aligned temporally with the temporal features of verbal information (durations of phonemes and pauses), are used for a lookup into Gesticon, in order to specify the best shapes V (or poses P), and trajectories T of the realization of the co-verbal behavior relevant to the entity generating them. In this phase, the algorithm moves from abstract/symbolic level to physical level, which has to take into account the motor capabilities of the virtual entities. When the behavior was aligned with the agent as well as the conversational context, a parameterization of the animation occurred (*Generation of the co-verbal behavior phase*). Each planned movement phrase is transformed into a symbolically, prosodically, and spatially coherent movement of an individual body part, described as a parametric configuration of agents' movement controllers propagating in defined time intervals. The description is specified in EVA-Script notation, which is understood by the EVA U-Realizer (Mlakar et al., 2018), interpreting and animating it.

Personalized HCI Entertainment System

The proposed HCI interface, with a novel embodied conversation model, has been applied within the UMB-SmartTV (Mlakar et al., 2014) that is a proprietary platform used for personalized HCI entertainment solutions in intelligent ambient. Namely, it is a multimodal IPTV platform that links IPTV services with the intelligent ambient. The architecture is developed on an IP Multimedia Subsystem (IMS) (Anis et al., 2012), and distributed DATA (Mlakar et al., 2013) distributed system extended with a cloud-enabling application framework. IMS is the core technology of the Next Generation Network (NGN) (Wilkinson, 2002), and is a platform of integrated multimedia application services to provide advanced, personalized functionality and content to the users. In a UMB-SmartTV, the IMS network provides basic communication functionalities like establishing audio and video calls. The IMS network is extended to provide additional functionalities, like network phonebook, presence and video conferencing (Jegade et al., 2010). For integration of IoT devices in intelligent ambient, a SIP application server provides gateway functionality between the IMS network and the IoT devices using an MQTT protocol. Environmental parameters are gathered from sensors, and relayed to the cloud-enabled DATA application framework. Its DM module makes an intelligent decision based on the data, and provides advanced user-centric adjusting of the environmental parameters. The DATA framework also provides ASR, TTS and gesture generation functionalities. They enable multi-modal enriched communication with the user. On the client side, DATA enabled client is used, implementing DATA protocol for multimedia content delivery.

Distributed Message-Oriented Core Server

From the system architecture point of view, many parts of the proposed HCI solution are very diverse, running from small embedded IoT systems on customer premises to applications and services running on HPC clusters located in the cloud. To be able to integrate these parts in a coherent entity, which is operating transparently for the user, a core server was implemented using a message-oriented queue middleware Gearman (Ewart, 2013). The three-tier design offers complete isolation and separation of functionalities into small logical entities that can be distributed over a large number of different machines. The core server's main objective is sorting received tasks from "clients" into queues, prioritizing them, and dispatching them to the appropriate processing server - called "worker" - without the implicit need for the client to know the final destination. High availability of the core server is achieved with clustering and persistent queues. Examples of clients include IPTV STBs and smart thermostats, which communicate with worker processes that are providing information and controlling the environment, heating, presence, lighting and other ambiance-related devices. In this way, the UMB-SmartTV merges IPTV services, intelligent-ambiance services, and a conversational agent flexibly into a personalized and embodied conversational interface.

ADVANCED SERVICES IN INTELLIGENT AMBIENT

Thus, the traditional intelligent ambient services are enhanced with the state-of-the-art Human-Computer Interface technology, enabling them to process, drive and react in a human-like fashion by utilizing auditory and visual channels in embodied conversation.

An example of such advanced intelligent ambient service, which makes a profit from improved naturalness in the communication are e-Health services and ambient assisted living paradigm (AAL).

The intelligent ambient can be applied as an ambient assisted living environment, which can be used to ease and support the independent living style of elderly users. An example of such a platform, primarily targeting the well-being of a person, is outlined in Figure 3. The ELU, outlined in this paper is extended with a virtual coach and biomarkers indicating the user's health. In this way, the coaching can rely on causal models of machine-user interaction which applies emotionally-believable adaptive responses of the virtual coach, keep off loneliness, sustain informed health status, enhance quality-of-life and simplify access to telecare and medical services. Such an agent knows when to start an interaction with the user; it is able to give advice; explain and motivate behavioral change in user's everyday life. In the system, outlined in Figure 3, proposed system the virtual coach measures the index for the holistic health/wellness status an elderly person by fusing the available vital signs, biomarkers, behavioral information and other information sources. The coaching logic can then select and schedule appropriate personalized coaching programme aligned (e.g. exercises, nutrient, etc.) with the person's individual needs and available resources.

In order to implement human-like and conversation oriented interaction, the ELU is utilized to fuse audio-visual sensing along with word sequences generated by Automatic Speech Recognition into an idea/concept regarding user's request, emotional state, and even expectation, giving the system a more detailed psychological state of the person. The ELU is used to define textual, expressive and semantic components of the response and fed directly to the text-to-speech engine (TTS) to express the communicative goals via the auditory channel (e.g. what to say). The Visual articulation of spoken content incorporates the non-verbal complements defining the nature of non-verbal representation (e.g. how to say). Through these complements, the conversational concepts are transformed into gestures and expressions synchronized with speech. The human-like embodied entity (e.g. embodied conversational agent) can express the generated communicative signals in form of non-verbal signals (gestures, postures, gaze, facial expressions and emotions) symbolically and temporally aligned with speech. Thus, the virtual coach notifies the user about the necessary steps/actions and outlines the obtained results to him/her.

Figure 3. A three-layered architecture of an advanced AAL framework supporting causal models of machine-user interaction

Architecturally, as outlined in Figure 3, the first tier of the proposed system is the Edge environment. It is physically situated in the user's domestic environment. It is built around the body (BSN) and remote sensor networks (RSN) with the ECA supported UIs as a centerpiece. 'Coaching' and interaction goals will be conveyed via friendly, empathic embodied conversational agents (ECA). The second tier is the walled garden - a closed ecosystem with restricted convenient access to non-approved applications and content. This layer isolates each user environment and hosts the cloud-based Coaching Logic (Coach) Conversational Logic (dialogue manager – DM, spoken language understanding – SLU, and natural language generation – NLG). The SLU facilitates the understanding of conversational signals generated by the user and, the NLG generates human-like conversational signals for personalized persuasive communicative and non-communicative interaction. The final layer consists of a dedicated and secured cloud environment which hosts the Cloud-based System Data Analysis framework (SDA) with services making 'general' and anonymized decisions. Each 'garden' instance sends irreversibly anonymized data to the big-data analytics framework.

Another important aspect of AAL is also the support of rehabilitation. The last phase of rehabilitation is, typically, carried out in the patient's home environment. As the patient is not being monitored directly by medical professionals, a lack of motivation can occur, and reduce the effectiveness of the rehabilitation procedure. The proposed system, outlined in Figure 3 can be used in intelligent ambient to remind and notify the patient when the next rehabilitation session takes place. Moreover, the agent can be applied to increase the user's motivation, with approaches such as presenting the patient with the positive development of his condition, which can be attributed to the past rehabilitation sessions. The Human-Computer Interface input modalities can be used additionally to supervise the user's rehabilitation session, and estimate the effectiveness and output of the session directly. The success of such e-Health services is tightly connected with the usage of advanced communication interfaces, which can produce natural and personalized interaction.

FUTURE RESEARCH DIRECTIONS

Speech, as an input modality for intelligent ambient, has proved to be an efficient way of communication. There are currently different implementations of virtual agents, with support for Automatic Speech Recognition available on the market. They provide Automatic Speech Recognition successfully for typical every-day scenarios in major world languages. The achieved speech recognition accuracy is in the range between 90% and 95%, which gives enough accurate information to the next processing modules, like the Natural Language Processing system.

The future trends in the area of Automatic Speech Recognition for intelligent ambient will focus on those scenarios where robustness against the degradations present in the input speech signal plays an important role. One of such sources of degradation is ambient and background noise, which is frequently present in intelligent ambient. Another important direction for future work is the support for low-resourced languages, which is a crucial step to enable the usage of spoken input modality in intelligent ambient for unsupported languages and new markets. Two main research directions can be observed in the area of low-resourced languages. The first one is trying to reduce the amount of spoken language resources which is needed to be able to train the Automatic Speech Recognition system. The second research direction is devoted to crosslingual speech recognition, with the objective to transfer the Automatic Speech Recognition system or spoken language resources from the source language to the target language. Cur-

rent research approaches show promising results for similar languages belonging to the same language group, but further research work is needed for less similar languages.

Further, the multimodal user interfaces have to be simple, intuitive, natural, and should adapt to a user's abilities with regard to the processing of natural and cognitive information and presentations. In intelligent environments several devices and AI technologies are being designed at a rapid pace. Nevertheless, the progress results in bigger interactive complexities, and, therefore, influences the perceived added value of these new technologies. Therefore, human-machine interaction and personalized interfaces have to start to drive not only the user experience, but also the 'penetration' capabilities of these technologies as a whole. In order to engage with a human user on a more personal level, natural human-machine interaction has to start to virtualize itself, and to utilize the potential of entities resembling human collocutors in interaction.

CONCLUSION

This article presented an overview of Human-Computer Interfaces in an intelligent ambient, with the specific focus on embodied conversation, which also utilizes personalization of the main interaction functions. The general building blocks of such an interaction system were presented, and an embodied conversational model was proposed. The objective of the proposed system is to establish the most natural way of communication, which is feasible with current state-of-the-art algorithms and methods. The outcomes and future research directions show that this research field still presents some very challenging topics, which need to be addressed in the future.

KEY TERMS AND DEFINITIONS

Automatic Speech Recognition: An approach of recognizing an uttered speech signal into a computer readable text.

Deep Learning: Part of Machine Learning, where methods of higher complexity are used for training data representation.

Emotion Recognition: An algorithm which recognizes human emotion automatically from various input signals.

Feature Extraction: A digital signal processing algorithm, which extracts distinctive values from the input signal.

Gesture Recognition: An approach to recognize gestures produced by a human during communication automatically.

Intelligent Ambient: An environment where various devices, algorithms and processes capture input signals and produce optimal environment conditions based on captured data and previous knowledge, applying Artificial Intelligence.

Multi-Modal: A procedure or algorithm which incorporates different types of modality and processes them to a single end result.

Personalized: An approach where parts or functions of a system get adapted to the particular end-user.

Text-to-Speech Synthesis: An approach where a system generates output audio signals from input text.

Integrated Electronic HEI Performance Management

Teay Shawyun

 <https://orcid.org/0000-0001-6760-0930>

King Saud University, Saudi Arabia

INTRODUCTION

Organization performance has traditionally been in the forefront of public and private enterprises on the rationale of strategic and operational process efficiencies and results effectiveness of value creations. Over the past decades, HEIs (Higher Education Institutions) as organizations offering educational values have slowly embraced the more business oriented management fundamentals to manage the HEIs professionally albeit profitably in its educational value creations to the students' effectiveness and employability. These managerial practices are more visible in the planning, quality assurance and accreditation pursuits and OBE (Outcome based Education) that forms the foundation of the HEIs assurance in meeting the market and societal needs of solid and quality education experiences and values to the students who represent the future of any society (Sousa, et.al., 2014; Hazelkorn, 2007).

All these managerial and quality endeavors are linked to the programs and institutional strategic and operational plans resting on huge disparate silos of data and information from academic-administrative units. Inadvertently colleges/programs/HEIs are asked the very basics of their outcome based accomplishments and achievements that encompass the performance management fundamentals. HEIs have harped on IR (Institutional Research) to holistically link educational quality assurances practices to planning underpinning students' performance and effectiveness through the wealth of data crunching and mining critical to the performance management for the colleges/programs/HEIs (Dawson, et.al., 2016; Hrabowski, Suess & Fritz, 2011a, 2011b; Picciano, 2012; Brudan and Zarnescu, 2015). These existing IR practices and performance management can be enhanced and expanded through an integrated electronic system that seamlessly extracts data from student, faculty, infrastructure and resources administrative and academic silos channeled towards the educational applications and colleges/programs/HEIs management and their re-invention (Clarke, Nelson & Stoodley, 2013; Hilbert, 2013).

While most HEIs have their customized Information System supporting planning, quality-accreditation- information-planning management in one form or another, these are exclusive within the HEIs context and needs. Of the research publications of these systems in support of informed decisions, there is a lack of in-sights into a holistic integration of the quality-planning-information systems that are used to prepare the operational course-program-self-study reports and performance metrics that links the planning-information duo from operational-tactical-strategic levels by faculty-program/college/institutional management based on data analytics. As such, it is posited in this chapter that the strategic triangularization of the QPIT (Quality-Information-Planning Troika) can lead to the development of an integrated electronic quality-planning-information system linking the IR (Institutional Research) goals to meet the faculty-program/college/institutional management needs and expectations based on data-performance analytics. This integrated electronic QPIT management system underscoring educational performance management is advocated to create and deliver on better value added education performance

DOI: 10.4018/978-1-7998-3473-1.ch077

of educational value meeting stakeholders-society-students' needs, HEI basic accountability of its stated mission through the proposed integrated systematic electronic PMS (Performance Management system) that closes the theoretical and practicalities gaps an electronic education performance management system.

Based on the rational above, this chapter proposes an integrated electronic system that links the QPIT (quality-planning-information troika) which is the basic foundation of performance management in any organization or organizational units. A leading university in the Middle East case study is used to illustrate this integrated electronic performance management system (e-PMS). Since 2016, the Phase 1 of the e-QMS (Quality Management System) (Teay, 2017) has been applied to the institutional-programmatic quality-accreditation management. The Phase 2 encompassing the development of the full-fledged ITQAN 2020 PMS (Performance Management System) is aimed at linking the quality-accreditation-planning management via information management and the use of BI (business intelligence) tools for its data and its learning analytics and methods (Avella, et.al., 2018; Daniel, 2015; Elias, 2011; Dekker et al., 2009; Feng et al., 2009; Ming & Ming, 2012) to support better informed decisions (Educause, 2010; Baker, 2007; Teay, 2018).

BACKGROUND: PERFORMANCE MANAGEMENT IN ENTERPRISES AND HEIs

The world is facing digital disruptions that could potentially affect the redundant value-chain activities or repetitive manual work (Dawson, et.al., 2016) of not only operational work in enterprises but also administrative-academic work in HEIs. The operational mundane administrative works run from developing the semester course specifications and reports, annual program specifications and reports to the 5-years program self-study reports. At the tactical level, department heads need better understanding of the student effectiveness through performance analytics. These cover a wide range of administrative and operational data gathering processes aimed at assessing institutional/collegial/programmatic performance and progress in order to predict future performance and identify potential issues related to academic programming, research, teaching and learning (Hrabowski, Suess & Fritz, 2011a, 2011b; Picciano, 2012). The strategic level decision making covers fiscal sustenance and enrolment strategies, programs offers and closures, infrastructural and resources planning and management efficiencies and effectiveness.

"Data and information is power" mentality has always been key organizational barriers in performance analytics and management (Kellen, et.al., 2013). Additional issues include: (1) pulling "quality" data out from all legacy systems silos across an enterprise, breaking out of "we know mindset" by pulling and linking them together so that the management or staff can look at them in any one of 50 or 100 dimensions, and (2) having capabilities and transferrable skills when adopting new technology to bridge the technical and the business sides (Manuel et.al., 2016; Kellen, et.al., 2013). This highlighted a McKinsey survey of 519 executives representing the full range of regions, industries, and company sizes that indicated high performers attributing their data and analytics success to involved leaders, while low performers say their biggest challenge is designing the right organizational structure for analytics activities (Brown and Gottlieb, 2016). In a bid to improve performance, GE, the Gap and Adobe Systems (Vara, 2015) dropped ratings, rankings, and annual reviews practices. The focus shifted from accountability to "learning" and development, centrality of team working and agility (Cappelli and Tavis, 2016). This rethinking of performance management would mean collecting more objective performance data through systems that automate real-time analyses with a shift in emphasis from backward-looking evaluations to fact-based performance and development discussions (Ewenstein et.al., 2016).

In its 2015 Performance Management State of discipline report (Brudan and Zarnecu, 2015) the KPI Institute reported key trends and challenges as:

1. **Trend Towards Integration:** The trend is towards data visualization through graphics focusing on individual and organizational goals in a collaborative work environment. These goals need cascading to all levels to improve productivity, innovation and governance (Clarke, Nelson & Stoodley, 2013) and integrating data from different systems which are the zenith of effective planning through alignments of objectives across all levels regardless of private/public organizations.
2. **Challenges:** Key challenges include: (1) performance definitions, (2) setting appropriate goals, (3) creating and motivating compelling performance management by the people, (4) interconnected practical systems, (5) people engagement and commitment at all levels, (6) informed decisions based on ability to obtain, analyze and report specific data within acceptable time frame to arrive at improved outcomes through business intelligence (Educause, 2010; Baker, 2007), (7) providing visibility and clarifying accountability issues, (8) building action plans through initiatives with KPI measurements that are minimally invasive and inexpensive, and (9) managing data at the scale of the Internet (Avella, et.al., 2016; Baker & Siemens, 2013; Dean & Sanjay, 2008).

A HEI, like any other organization, has specific processes that support the achievement of its teaching-learning-research missions and contribution to academic and societal development of the community and stakeholders at large. These three key processes (Ashworth, 1999; Childe *et al.*, 1994; CIM-OSA Committee, 1989) as adapted to the HEI as a value creating organization are the:

1. Operational educational processes that create, produce and deliver on educational value,
2. Academic and administrative support processes that support the operational processes and provides added value to the basic educational value (Garvin, 1998; Porter, 1980), and
3. Administrative and management processes encompassing the goal setting, controlling and organizational behavior processes.

Verweire and Van den Berghe, (2003) argued that all these processes supporting integrated performance management needs both strategic and maturity alignment of appropriate managerial and operational processes for performance measurement and management. This underlies the imperatives that ethical performance management in the HEI must move from a monitoring stance to that of management focused on strategy (Cullen, *et al.*, 2003). It should support management through measurement (Bourne, *et al.*, 2005) that highlights the internal context factors that are interactive in nature and are much more complex than the existing simplistic physical and formal systems affecting performance. The performance model of Martz (2001) for a HEI setting had the principles to define performance expectations, create attainable but challenging goals, furnish clear measurements, encourage involvement and provide process clarity and feedback.

ANALYTICS IN HEIS

McKinsey Global Institute (2011) reported that Big Data is the next frontier for innovation, competition and productivity. Business intelligence and analytics (BI&A) data science means that enterprise data management and advanced data, text, and Web analytics are essential and critical for turning data into

actionable insights and intelligence (The Economist Intelligence Unit 2011; Russom 2011). Demand for BI&A has been demonstrated by a number of studies (LaValle et al. 2010, 2011).

Key issues facing accountable and transparent governance of the 21st century HEIs in this disruptive digital era include increasing enrollment, ensuring students effectiveness and employability of graduates, reducing tuition and costs (Thornton, 2013) through educational value re-creation and re-inventing learning experience and be an accountable and transparent corporate citizen (Sousa, et.al., 2014; Hazelkorn, 2007). This has compelled HEIs towards better understanding the strategic enrollment, student retention and learner engagement through course re-design from the applicants and students' context. This includes tracking enrollment trends and educational data mining research through psychometrics statistics, information visualization, and computational modelling in a forward thinking manner (Baker and Inventado, 2014; Baker, 2013; Romero and Ventura, 2010 and Baker & Yacef, 2009; Norris et al., 2008). Infrastructural support includes fiscal success through comprehensive data comparatives and analytics, efficiencies and effectiveness of IR (Institutional Research) and the HEI ICT (Information Communication Technology) ability to support the institution's data availability-access-analysis to transform management informed decisions (Boyd & Crawford, 2012). These call for the HEIs to seek to leverage their analytics capabilities and not in the technology per say but in the use of new technologies for data capture (Choudhury and Pentland, 2003) and advances in computation (Mayer, 2009). This calls for managing and making the most of opportunities that big data offers (Long and Siemen, 2011) that is "technologies and techniques that make capturing value from data at an extreme economical scale" (Yang, 2013) and the "three Vs" (Volume, Velocity and Variety) of big data (Douglas, 2001). The OECD (2013) report suggested that big data be more cost effective (Hilbert, 2013) to be the foundation where HEIs can reinvent their business model by bringing together the data analytics (Avella et al., 2016; Elias, 2011) for informed decision makings about educational outcomes.

These informed decisions are based on the INFORMS categories of analytics of "Three Big Data Analytical models in Higher Education" (Daniel, 2015). These three categories of analytics intersect each other to provide:

1. **Descriptive Analytics:** This covers describing and analyzing historical data collected on students, teaching, research, policies and other administrative processes (cf. Dekker et al., 2009; Feng et al., 2009; Ming & Ming, 2012). This can include analytics like course completion rates for a particular program over time or determining what were the attributes of the students who didn't complete successfully.
2. **Prescriptive Analytics:** This involves assessing their current situation and making informed choices on alternative course of events based on valid and consistent predictions to arrive at increasing student completion rates, reducing time to degree and minimizing excess credit hour accumulation. In essence, it is "using various technologies to uncover relationships and patterns within large volumes of data that can be used to predict behavior and events" (Educause, 2010) to "engineer positive changes throughout the student life cycle" (Eduventures, 2013).
3. **Predictive Analytics:-** This provide institutions/colleges/programs with better decisions and actionable insights based on data like predicting students who are exhibiting behaviors early in the semester which put them at risk for dropping or failing a course or the predicted course completion rate for a particular program and which students are currently at risk for failure.

Addressing these challenges, Kellen et.al., (2013) case study of HEI's big data analytics and architecture recommended: (1) open access to data and front-end neutrality through Big Data and other BI

(Business Intelligence) opportunities, (2) build architectures that promote copying and reuse, (3) engaging the community throughout the process to collect valuable feedback and build new designs quickly that the community needs (Dringus, 2012; Dyckhoff et al, 2012; Wagner and Ice, 2012). Long and Siemen (2011) and Avella et al. (2016) indicated, “Big Data is now well positioned to start addressing some of the key challenges currently facing higher education”.

A UK Higher Education Commission Report highlighted that “Fluid data has the potential to provide an instant, accurate picture of how a student is performing” to be collected, linked and analyzed. Part of the 12 recommendations of this report include using learning analytics as the measurement, collection, analysis and reporting of data about learners for the purposes of understanding and optimizing learning and the environments in which it occurs. The Commission emphasized the need for institutions and leadership of achieving their strategic goals by ensuring that digital literacy, capability and good data management strategies being an integral part of the HEI strategic plans. They indicated that learning analytics provide huge benefits for their students by introducing appropriate learning analytics system to identify and foster excellent teaching, improve student support and institutional performance. The learning analytics definitions, processes and potential of Elias (2012) and the methods, benefits, and challenges in Higher Education by Avella et.al., (2011) discussed the state of art and their great and untapped potentials to benefit the HEI performance management and its use and understanding of data and learning analytics of its systems and schools to deliver on educational value greater process efficiencies and result effectiveness. These benefits include identifying target courses, curriculum improvement, student learning outcome, behavior, and process, personalized learning, improved instructor performance and post-educational employment. The challenges include data tracking, collection and analysis, evaluation process, learning sciences connection and environment optimization, emerging technology and ethical and privacy issues

METHODOLOGY IN DEVELOPING INTEGRATED E-PMS (ELECTRONIC PERFORMANCE MANAGEMENT SYSTEM)

While education excellence is an aim, this must be translated into functional and operational systems-mechanisms that drive performance excellence in education as enshrined in the education criteria of MBNQA (NIST, 2015). In aiming to close the theoretical and practicalities gaps of the design-development of an electronic education PMS (Performance Management System, a 5 step methodology is advocated:

- Step 1 **(Developing the KSU-IR Framework):** The KSU-IR Framework is the main foundation of a strong sustainable performance management system with use of planning-information-quality analytics for informed decision making. The data collations-extractions-processing-staging into information combines BI (Business Intelligence) and human heuristics-judgmental tactics to come up with educational knowledge and wisdom as opposed to subjectivity-emotional-political schemes dependencies.
- Step 2 **(Developing the QPIT Framework):** The KSU-IR defines the data-information-knowledge of the academic system requirements underlying the interdependencies and integration QPIT domains that should not be addressed independently as mostly effected by most HEI. The QPIT identifies the key requirements linkages across the quality/accreditation-planning-information domains-management systems that are critical to an integrated electronic education performance management system.

Figure 1.

Step 3 (Developing the IPOO Architectures): The QPIT is used to define the architecture and schematic electronic modules of the quality/accreditation-planning-information that includes the performance/statistical-data metrics, internal audit & assessment/scoring, learning outcomes design-development-teaching strategies-assessment, DBMS (database management system).

Step 4 (Integrated Electronic PMS): The QPIT & IPOO architecture culminates in the PMS data entity & applications processing management as a holistic electronic academic system applications working in tandem interactively to meet the performance management needs of the stakeholders.

Step 5 (**Sample Screenshots of actual PMS**): These depicts some of the main quality/accreditation-planning-information modules and the strategic-operational dashboards data analytics of the PMS.

STEP 1: DEVELOPING THE KSU-IR (KING SAUD UNIVERSITY INSTITUTIONAL RESEARCH) FRAMEWORK

It is important to note that the QPIT is the basis of operationalization of the KSU-IR framework (Figure 2) that links quality-accreditation-planning management via the information management of data analytics. Key contributions of IR to planning, decision-making, and policy formulation where IR can contribute to programmatic/collegial/institutional informed decision making through data analytics (Saupe, 2009; Sousa et. al., 2014) are:

- Determining how the institution's publics perceive its missions and goals by assessing institutional outcomes and accomplishments, pointing to areas where performance does not meet expectations and develop strategies for improvement; facilitating institutional self-study and accreditation-accountability-performance processes-mechanisms and resources utilization.
- Contributing to program planning-development by intensive programs-departments reviews; reviews and revisions of curricula based on students' course-selection behavior; faculty grade-giving behavior and students grade-earning behavior.
- Studying the faculty-students and administrators-management culture-values-norms diversity and extent to which the culture-values-norms effects on inform the planning-policy directions and understanding potential obstacles to moving in new directions.
- Improving process-procedures instruction and specific instruments used in the evaluation of instruction and instructional methods and media.
- identifying instructional activities and allocation of resources inefficiencies with data on class sizes, teaching loads and student-credit-hour productivity made available to academic administrators.
- Providing enrolment projections-analyses trends and relationships which guide enrolment policy and suggest enrolment planning assumptions-strategies through student body data, retention and attrition data, causes of attrition and on strategies for increasing retention that can contribute to maximizing society's investment in education.
- Supporting inclusive education to special types of students by assessing their preferences, predispositions and academic behavior like part-time/minority-group students, women/LGBT students, talented/handicapped students, older-others students who differ from the traditional student.
- Assisting access to the college/university educational opportunities by informing applicant's choice institution; developing/availing consumer information to prospective students; determining students' financial affairs used as consumer information as well as referents for the determination of financial aid programs and policies and determining program effectiveness of financial aid in achieving the program goals that can be evaluated with the evaluation leading to improved financial aid resources use.
- Evaluating and improving academic advising/counseling, career planning/placement, intercollegiate activities, health services and housing.
- Contributing to the institution's development program through institution information used in proposals for specific projects external funding; fund-raising campaigns; and designing information-based strategies for seeking donations from foundations, corporations, and individuals.

Figure 2.

Source: Adapted from AIR (Association for Institutional Research) 2017, *Development of Duties and Duties & Functions of Institutional Research*, FL, U.S.A., <https://airweb.org/>

Figure 2 : KSU-IR (Institutional Research) Framework		
	Duties	Responsibilities
	1. Identify information needs	- the iterative process of identifying relevant stakeholders and their decision support needs - assisting stakeholders in developing and refining research questions
	2. Collect, analyse, interpret, and report data and information	- provide data, information, and analysis for decision support - process of collecting and reporting required and requested data - incorporates applied research methods to analyse data to provide information for decision making, including appropriate interpretation of analysis results
	3. Plan and evaluate	- Planning may include operational, budgetary, and strategic planning - include program review, particularly for accreditation purposes - Formative and summative evaluation processes conducted at an institution use IR data and analysis for planning and <u>decision making purposes</u>
	4. Serve as stewards of data and information	- institutional research's role in ensuring an institution-wide data strategy (privacy and security and ethical issues) - data quality assurance activities - ensuring data are appropriately accessible and usable to those who need them to make decisions
	5. Educate information producers, users, and consumers	- training and coaching related to the use of data, analysis, and information to inform decision making - ensuring the ability to collect, access, analyse, and interpret information independently and in collaboration with other stakeholders - Scholarship to inform and improve data, information, and analysis for decision support

STEP 2: THE QPIT FRAMEWORK OF KSU ITQAN 2020 E-PMS CASE STUDY

The rationale of the QPIT underscoring the ITQAN 2020: KSU-PMS supports Andersen *et al.*'s (2006) holistic approach of harnessing the various tools and concepts into an overall framework where their inter-linkages are understood when responding to the internal and external challenges. While most of the frameworks look at the macro or big picture, Rouse and Putterill (2003) proposed a macro-micro linkage and moving from organizational to operational levels of: 1) interface between organization and stakeholders, 2) resources capacity-capability, 3) planning-evaluation and resource-achievement, and 4)

Figure 3. Quality, planning and information troika (QPIT) framework

input-activities-output core elements, are key determinants of success. This supports Franco-Santos *et al.*, (2007), Bernardin *et al.*, (1998), Kennerly and Neely (2002), Harrington (2005), Newkirk-Moore and Bracker (1998), Temporal, (1990), Bolt, (1993), Burach *et al.*, (1997), Tovey, (1991) and Mason, (1993) macro-micro organizational and management views that were not clearly nor specifically addressed.

The QPIT (Figure 3) demonstrates a seamless quality-planning-information management platform principal to the integrated inseparable and interdependent performance management that are the three key strategic pillars of KSU 2030 “Towards Excellence” Vision and Mission covering:

1. **Quality Management:** Addresses all aspects of continuous improvements of quality & accreditation management meeting academic & educational services & support requirements of national & international accreditation.
2. **Planning Management:** Addresses strategic and annual operational planning of all academic & administrative units inclusive of developmental planning from quality & accreditation management.
3. **Information Management:** Addresses academic-administrative data, documentaries and information inclusive of strategic/tactical/operational performance-statistical metrics, data analytics and dashboards needs for evidence-based performance management.

STEP 3: DEVELOPING THE IPOO ARCHITECTURE E-PMS

The QPIT links the KSU-IR to the architectural development of the KSU ITQAN (Arabic term for Excellence) 2013-2015 e-QMS (Quality Management System). It is the base system to support the data analytics that all HEIs aim for. The basic rationale for the integrated e-QMS system is a robust electronic workhorse to address the demanding documents heavy, tedious and repetitive statistical requirements for the EEC-NCAAA (Education Evaluation Commission – National Center for Academic Accreditation

and evaluation) quality management/accreditation system of KSA (Kingdom of Saudi Arabia) and the newly established SAQF (Saudi Arabia Qualification Framework) in 2018.

Figure 4. KSU ITQAN 2020 Integrated Electronic Performance Management System

The full-fledged ITQAN e-PMS (electronic-Performance Management System) architectural platform (Figure 4) has two main phases of:

1. **Phase 1 (2014-2016) e-QMS** of achieving efficient and effective institutional-collegial-programmatic quality/accreditation management and functional-operational course/program/ self-study specifications/reports by programs in all colleges.
2. **Phase 2 (2018-2020) e-Planning & e-Performance** constituting the integrated planning-performance management platform with e-QMS meeting critical performance needs and requirements of

academic/administrative planning-quality-accreditation assurance, data analytics and performance management.

Basically, the ITQAN e-PMS architecture has three main operating components of its Inputs/Processing/Outputs & Outputs-Users (Figure 4) as follows:

1. **INPUT Component** – Constitutes the common data sources for functional-operational data management in quality/accreditation/planning/performance management from the various data sources across the whole institution.
2. **PROCESSING Components** – Constitute the main processing system that houses two main components of:
 - a. **DBMS (Database Management System)** – This DBMS extracts-prepares-processes-stages all statistics & data from the data sources used in the quality-accreditation- planning-performance data-marts for the e-QMS and e-PMS applications software.
 - b. **E-(Electronic) E-Quality, E-Planning, E-Information and E-Performance Management Application software** – Covers all the existing e-QMS and new e-PMS functional-operational modules as follows:
 - c. **E-QMS:** Full functional aspect of e-QMS modules for institution-college-programs quality-accreditation management with updated modules of:
 - i. **E-Curriculum Mapping Module and E-Course/Program/Self-Study Modules:** Reflect and support both new EEC-NCAAA/EEC-SAQF in-depth system requirements. This brings about modifications to the templates and statistical data requirements of Course/Program/Self-study requirements.
 - ii. **E-Performance Metrics & KPIs:** A new set performance-statistical data metrics will bring about a new set of aligned quality-accreditation-planning-performance metrics and data analytics to support strategic/tactical/operational performance management and informed decision-making by all KSU units.
 - d. **E-Planning Management:** Addresses the Strategic/Annual operational-developmental planning for all academic-administrative units' functionality development and planning monitoring and management tied to quality management.
 - e. **E-Performance Management:** Addresses the Strategic/Tactical/Operational performance metrics of academic-administrative units' performance monitoring-management that are aligned across board in KSU with data analytics and dashboards supporting informed decision-making and actions.
 - f. **E-Academic Development & Course/Faculty Portfolios Management:** Addresses the Vice Rectorate of Academic Affairs needs of Program development-updates-monitoring-management that are inclusive of E-courses/faculty portfolios.
 - g. **E-Societal Responsibilities Management:** Addresses capturing-reporting of all societal responsibilities activities by all KSU units.
 - h. **E-INTERNATIONAL & E-ISO Accreditation:** Address the colleges/programs international accreditation & administrative units' ISO certification of quality assurances.
3. **Enhanced E-Supporting E-Modules:** The following (1) e-Performance Metrics; (2) e-SID - (Statistics, Information & Documents); (3) e-Statistics, (4) e-Surveys (5) e-Faculty Portfolio, (6) e-Business Intelligence Queries & Analytics and (7) e-Student Portfolio, are all enriched to meet the enhanced functional and operational needs of the e-PMS.

4. **E-OUTPUT & E-USERS Components** – This identifies the two main aspects of the key users-outputs of the e-PMS as:
 - a. **Users:** The 5 main users are: (a) Programmatic Self-Study Teams (b) Faculty (c) Program Committees (d) Board of Assessors and (e) academic-administrative decision makers. The integrated power of data queries-analytics is used by all administrators for informed decision making and actions underscoring the KSU-IR Framework.
 - b. **Key E-Outputs:** Main outputs from the e-PMS are used for: (a) quality-accreditation management of courses/programs and students' effectiveness-efficiencies and, (b) well planned and actioned performance accomplishments-achievements management to support informed decision making and actions with key outputs as follows:
 - i. E-Program Specifications-Reports (PS-PR)
 - ii. E-Course Specifications-Reports (CS-CR)
 - iii. E-SSRI and E-SSRP (Self-Study Report – Institution and Programs)
 - iv. E-SESRI and E-SESRP (Self-Evaluation Scale for Institution and Programs)
 - v. E-QPAR (Quality Performance Assessment Report)
 - vi. E-Quality-Accreditation and E-Planning-Performance monitoring-management performance reports
 - vii. E-Strategic-Operation-Developmental Plans
 - viii. E-Strategic-Tactical-Operational Performance Metrics & data analytics and E-Management queries, E-dashboards, routine and ad hoc E-reports.

STEP 4: DEVELOPING THE ITQAN PMS AND IMPLICATIONS AND DISCUSSION

In essence, the QPIT and architectural components is transformed into the integrated electronic platform of the ITQAN 2020 e-PMS architecture modular components and configurations (Figure 5) with 3 main sub-system components as follows:

1. **E-Data Entity Management:** The main purpose of this entity is to provide clean-correct common datasets in the DBMS used for the quality-accreditation-information and planning-performance management. These data are sourced, cleaned and validated as reliable/valid common datasets for the ITQAN processing management system. Basically this is a core critical data sourcing-capturing-cleansing operation for validity-reliability from data silos across the academic-administrative units. They are processed-computed-staged as datasets for application data marts in the ITQAN e-PMS applications.
2. **ITQAN e-PMS:** The e-PMS has two main processing mechanisms of: (a) the common datasets inputs from the data entity management data/statistics processing used for quality/accreditation/planning/performance management (b) the statistical data and performance metrics staging to the EEC-NCAAA and KSU-QMS templates and tables for Course/Program/Self-study/accreditation management, SID management, performance metrics & surveys, internal audit and assessment & performance scoring, and alumni/employment markets and societal responsibility and community services management applications. The components of the ITQAN processing management is comprised of:

Figure 5. KSU ITQAN 2020 Integrated Electronic Performance Management System

- 12 modules of the *ITQAN e-QMS & accreditation modules* (Figure 5) that are basically the heart of the system underscoring the main quality/accreditation development-monitoring-management of academic units processing components meeting EEC-NCAAA requirements;
- 3 modules of the *ITQAN e-Planning Management & BSC (Balanced Scorecard) module* for all academic-administrative units' strategic-operation-developmental planning-monitoring-management through the BSC approach; and
- 3 modules of the *ITQAN e-Performance Management module* for the academic- administrative units performance monitoring and management supporting informed decision making through data analytics.

3. **E-Performance Management:** This represents the main utilization of the data & performance analytics and information from the base systems (1) & (2) for data and learning analytics. As noted in the data analytics section above, the courses-programs, academic-administrative units data entities provide a huge pool for data and learning analytics applications as:
 - a. ***E-Informed decisions and actions for performance management*** by all levels of institutional/collegial/programmatic/individual users of data-statistics-information for objective informed decision making as opposed to subjective-heuristic behavioral-judgmental decisions. These cover the individual student/faculty performance and effectiveness analytics in support of increased curriculum development-design-implementation and infrastructure/resources management efficiencies and effectiveness. These include: (a) descriptive analytics of students, teaching, research, policies and other administrative processes (cf. Dekker et al., 2009; Feng et al., 2009; Ming & Ming, 2012); and (b) Prescriptive and Predictive analytics to uncover relationships and patterns within large volumes of student/faculty/program/resources data to predict behavior and events (Educause, 2010) for effective positive student/program change throughout their life cycle (Eduventures, 2013).
 - b. ***E-Quality and accreditation management*** that increases productive efficiencies and effectiveness levels by minimizing manual based quality fatigue and zeroed in on evidenced based performance management of its course/program & student/faculty analytics (Norton, Porter and Shacklock, 2016; Dringus, 2012; Dyckhoff et.al, 2012; Wagner and Ice, 2012; Elias, 2012 and Avella et.al. 2011).
 - c. ***E-Planning & E-BSC (Balanced Scorecard) management*** that brings about better development-implementation-management of the strategic/annual operation/developmental plans based on the recommendations of internal audit & assessment and accreditation. It highlights the imperative that the planning is linked to the quality and accreditation management as part of the QPIT and cause-effect data analytics and performance monitoring/management through the BSC framework aligning the performance across all levels.
 - d. ***E-Performance Analytics and business intelligence tools*** to support in-depth cost effective data analysis-modeling that forms the core of institutional research affecting informed decision making. This allows for drill-ups to institutional level or drill-downs to individual level to better customize program of studies based on better understanding of student/faculty performance (Yang, 2013; Douglas, 2001; Hilbert, 2013).

STEP 5 SAMPLES OF SCREENSHOTS SAMPLES OF ITQAN 2020 SYSTEM

Figure 6 shows the landing page of the two main e-PMS and the Performance dashboards that leads to: (1) the 12 modules of the ITQAN System on the left menu, and (2) the overall dashboard of the progress of institutional accreditation components and its drill downs (Figure 7).

Figure 8 shows the main sub-components of the administrative performance dashboard entry. These allows for drill-ups and drill downs, trend analysis across years or data points periods, or deep dive into a singular metric that needs more detailed analysis. Figure 9 illustrates a sample of the main summary of strategic performance metrics. These strategic level performance metrics can be customized based on key categorical areas of data analytics meeting different needs or requirements.

Figure 6. Landing page of the ITQAN Performance Management System

Figure 8. Landing page for all administrative units' dashboards

Figure 9. Dashboard of Strategic Performance Metrics

Figure 10. Strategic Planning Module of KSU 2030 Strategic Plan Mission, Vision, Values

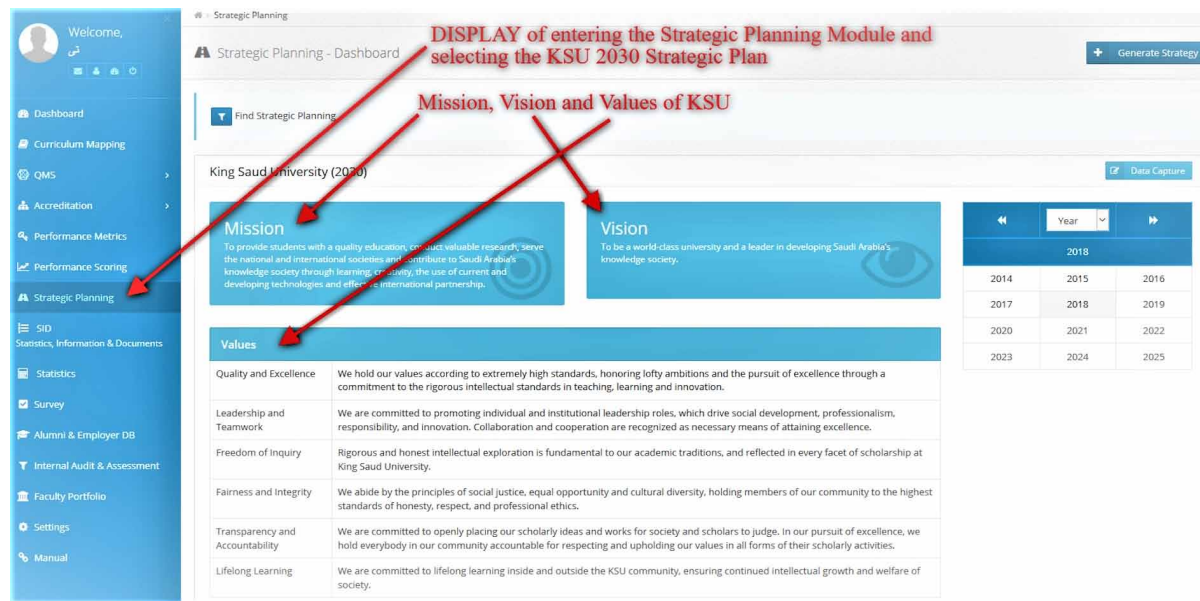

Figure 11. Dashboard of the main BSC (Balanced Scorecard) of Planning Module

Figure 10 shows the entry to the BSC system for strategic planning where the key Vision, Mission, Values and the goals and objectives are displayed. Figure 11 shows samples of the dashboard of the planning module.

IMPLICATIONS AND LIMITATIONS OF E-PMS

As demonstrated by ITQAN KSU-PMS the key implication is the integrated bridging of the ICTs and HEI quality-accreditation-information-planning-performance management electronically data analytics of its planning-performance educational aims and mission accomplishments that underscores the KSU-IR Framework. Key implications of the QPIT based e-PMS are:

- Bringing about an interdisciplinary interdependencies of the strategic management, education management with the IS/IT management as the enabler for QPIT management, that are aligned, to bring about the convergence of 3 very different disciplines and practices. This is done through the expert knowledge of the champion or change agent who has practical and working knowledge and skills of the strategic needs of the HEI and the operationalization of the technicalities of ICTs, data analytics and details of the tedious-overwhelming quality management and accreditation operational requirements.
- Moving from the macro organizational strategic educational needs to the micro level operational or functional educational processes-procedural needs. This calls for a new mind-set, new capability-capacity sets; new individual-organizational learning as cohesive and consistent entities moving in the same unified holistic mutually aligned strategic directions-accomplishments-achievements. The key factor is aligning-matching the college-program-faculty micro aspect operationalization of the institution macro overview through re-engineered internal processes-procedures and human capital.
- The core educational teaching-learning-research processes is strategically linked via the quality management with the ICTs supporting enablers and a set of strategic-operational-developmental plans that form the integration and electronic triangularization of the QPIT managed as a holistic whole than as separated parts.

As evidenced in another book chapter, the key limitations are mainly human capacity-capabilities inclusive of leadership-management mindsets-philosophies-values-pragmatics and bureaucratic silo focused organizational strategies-policies-processes-procedures and lack luster collaboration-cooperation that persists and impedes the e-PMS strengths and sustainably.

FUTURE RESEARCH DIRECTIONS

While this e-PMS is a robust QPIT linkage of seemingly diverse and disjointed quality-accreditation, planning-performance and information-data analytics systems enabled by ICT, key future research directions exist for more in-depth and interdisciplinary research into:

- Enhancing the education knowledge economy through a set of integrated data-performance analytics that covers the scale and scope of the HEI strategic-tactical-operational educational management integrated requirements, as opposed to a silo-based approach that undermines societal-stakeholders-students' needs-expectations-accountabilities;
- Incorporating the power of enabling ICT and data-performance analytics into the HEI educational strategic-tactical-operational management integration to minimize quality-accreditation fatigue, increased faculty-program-collegial-institutional educational productivity and better informed decision making by all internal-external stakeholders;
- Incorporating interdisciplinary business tools-techniques, strategic-planning-performance management competencies, quality-accreditation diaspora, human-organizational behavioral-attitudinal-values, ICT tools-techniques to create and deliver the societal educational values-needs-expectations; and

- Determining the educational value creation-delivery and educational accountabilities-responsibilities framework of the educational PMS towards students-faculty-institutional efficiencies-effectiveness paradigms.

CONCLUSION

HEIs have established IR for integrative quality, planning and information optimization through data analytics. The IR has been realized through various manual-computerized based systems that are potentially integrated or disjointed separated quality-accreditation- information-planning-performance management systems. The KSU ITQAN e-PMS case study chapter intends to highlight that an integrative PMS framework can be made more powerful through the establishment of an e-PMS through the QPIT.

On the quality-accreditation front, the tedious mundane document heavy processes have improved by 50% quality fatigue reduction and improving program/faculty efficiencies leading to better support and student/faculty effectiveness management. On the planning-performance front, planning is linked to the strategic/operational performance metrics thus closing the consistently weak quality-planning link. In effect, the e-PMS forms the core foundation for performance analytics to support better institution/program/student/faculty/infrastructure management through the data and learning analytics using the BI tools. While this e-PMS does not claim to be the best integrated system, it does demonstrate that integration of the QPIT can better support performance management in the institution/colleges/programs/students/faculty/resources efficiencies and effectiveness through its rich vast data and information analytics.

In conclusion, even-though the integrated electronic ITQAN 2020: KSU-PMS emphasized on the strategic QPIT integration, this does not mean that other concepts and frameworks are irrelevant. On the contrary, as noted by Andersen *et al.* (2006), the quality-accreditation-information and planning-performance management, or for that matter, all aspects of the HEI commitment of educational value to society must be approached from a holistic integrated perspective with an appropriate set of plethora of tools and techniques depending on the situational needs.

KEY TERMS AND DEFINITIONS

E-PMS: Performance Management is a process for establishing shared understanding about what is to be achieved and how it is to be achieved, and an approach to managing and developing people that improves individual, team and organizational performance (Armstrong M., 2006). e-PMS is the integrated electronic modular components of the HEI Quality-Accreditation- Information-Planning-Performance essential for student-faculty-programmatic-collegial-institutional efficiencies-effectiveness towards strategic-tactical-operational the mission-goals-objectives underscoring informed decision making.

E-QMS: e-QMS is the electronic version institutional-programmatic quality-accreditation management of core essential quality assurance managements policies-processes-procedures-people utilizing statistical data & performance analytics to prepare-process-audit-assess-submit self-study-program-courses continuous efforts towards accreditation.

Integrating Big Data Technology Into Organizational Decision Support Systems

Ahmad M. Kabil

University of Wisconsin-Whitewater, USA

INTRODUCTION

Organizational Decision Support Systems (ODSS) is defined as “a new type of DSS, focusing on the organization rather than the individual or the group,” (George 1992, p 109). With the growing trend of global competitiveness and business complexity, the design of ODSS faces two critical challenges (Jespersen, 2018; Garrido, 2015). The first is the high pace of decision scenario relative to the corresponding decision-making cycles. The second challenge is the large scale of volume, variety, and velocity of data that exceeds the capability of traditional databases and data-warehouses in the system. A proposal of meeting such challenges is to provide the decision-makers with the capabilities of allowing them to feel, recognize, abstract, comprehend, analyze, and decide faster than the scenario pace. Using Big-Data technology (BDT) in ODSS would provide the decision-making team with such faster decision-making capabilities.

The BDT is a high resolution representation of real life in such a way that all movements, activities, thoughts, conversations, relations, feelings could be tracked, recorded and processed almost online (Sagiroglu & Sinanc, 2013). Such BDT as an accurate representation of real life could be used in both ways, to understand the real life and to control it (Wu et al., 2014). Fast cycles of understanding and controlling real life situations are the key functions of ODSS. The need for BDT is well recognized on several decision-making levels. The “Global Pulse” is a recent initiative of the United Nations Secretary General for accelerating discovery, development and scaled adoption of Big-Data innovation for sustainable development (UN Global Pulse, 2015). The impact of BDT on the economy has been referred to as “the new oil” (Kolb & Kolb, 2013: p. 10).

The goal of this chapter is to describe a conceptual framework for integrating BDT with traditional designs of ODSS. The updated conceptual design is validated using the Analytical Hierarchy Process (AHP) and the Quality Deployment Function (QFD) technique. The QFD technique correlates the design modules to common ODSS requirements after prioritizing it through the AHP. The conceptual design provides a system that is flexible and responsive to decision makers’ need in developing their own ODSS. The initial stages required for implementing the conceptual design are given.

BACKGROUND

Decision support systems have traditionally supported the problem definition, alternatives development, alternatives analysis, choice, and implementation phases of the decision-making cycle. Courtney (2001) suggests moving from a classic decision-making paradigm model to a cycle that emphasizes synthesis and post implementation review as well as environment scanning.

DOI: 10.4018/978-1-7998-3473-1.ch078

Figure 1. From Big-Data to Decision in ODSS
(Adapted from Kabeil & Kabil 2018)

The quality of decision, such as any other engineering product, is built from the very beginning all through the decision processing cycle (Davern et al. 2008). The generic decision cycle starts with data gathering that is processed further to higher levels of information, knowledge, intelligence, wisdom, and decision. The decision is implemented to move a real-world-situation to be more suitable for the next decision or action (Kabeil & Kabil, 2018).

Leverage the “Data” concepts and technologies to “Big-Data” ones affects all higher levels of the model depicted in figure 1. Information is defined as useful data. Usefulness of data depends on the user, time and context of the use (Shankaranarayanan & Cai, 2006). Transforming data to useful information starts with data cleansing and interpretation, which has been changed with the radical increase of Volume, Variety, and Velocity of Big-Data (LaValle et al 2011).

In the model under consideration, knowledge is defined as the know-how of object or concept behavior. According to the United Nations Development Program (UNDP), knowledge management is defined as “the practice of capturing, storing and sharing knowledge so that we can learn lessons from the past and apply them in the future.” (UNDP, 2007: p. ix). Big-Data technologies open doors for new knowledge management methodologies using parallel processing on clusters of data servers (Cuzzocrea, 2014).

In the same context, intelligence is defined as the capacity of handling new situations. This definition is consistent with Wang’s definition, which considers intelligence as the capacity to adapt under insufficient knowledge and resources (Wang, 1995).

Wisdom is defined, in the same context, as the values, ethics and beliefs that form the preferences of a decision maker (Kabil & Kabeil, 2011). Bellinger, et al. (2004) present a model of Data, Information, Knowledge, and Wisdom hierarchy in both the Knowledge Management and Information Science domains.

Decision is defined as a selection of course of actions among several alternatives to interact with a real-world-situation according to a set of preferences that reflect the group wisdom. The decision is implemented through a Command, Control, Communications, Computers, Intelligence, Surveillance, and Reconnaissance (C4ISR) System to move a real-world-situation to next phase of expected scenario (McDowall, 2019). Using emerging technologies of Big-Data in ODSS is reviewed in next sections.

BIG-DATA TECHNOLOGIES FOR ODSS

There are several definitions of the term “Big-Data.” Perhaps the most popular definition is based upon the IBM’s differentiation of Big-Data according to 3 attributes of the 3 V words, Volume, Variety, and Velocity (Sagiroglu & Sinanc 2013; LaValle et al 2011). The “Volume” attribute of Big-Data reflects the large quantity of data being generated from various resources including data captured from different devices and sensors that are networked together as well as the information accessible on common social media such as Facebook and Twitter (Centola 2010).

The “Variety” attribute of Big-Data is referred to the numerous types and sources of data required to understand or control a situation. Big-Data goes beyond traditional structured relational databases to include less structured data such as weblogs, social media, e-mail, sensors, photographs, and videos (Sagiroglu & Sinanc 2013). The different kinds of data feature up to the level of individuals with highly various sets of structured, semi-structured, and unstructured data (LaValle et al 2011).

The “Velocity” attribute of Big-Data represents the high dynamics of situations under investigation and the rapid change in data over time (Sagiroglu & Sinanc 2013). As the world becomes more developed and connected, as the dynamics of situations and change in data increase.

After reviewing several definitions of Big-Data, De-Mauro et al. (2014) provide a consensual definition that synthesizes common themes of reviewed definitions as “Big Data represents the information assets characterized by such a high Volume, Velocity and Variety to require specific Technology and Analytical Methods for its transformation into Value” (p. 8). Such a definition of Big-Data points at its need for specific technologies and analytical methods.

The main technologies and analytical methods used for creating Big-Data as reported in literature are Crowdsourcing, Location-Based Services (LBS), Radio Frequency Identification (RFID), Near-Field Communication (NFC), Remote Sensing, and Big-Data analytics.

Crowdsourcing

Estellés-Arolas and González-Ladrón-de-Guevara (2012) conducted a comprehensive study to reach a consensual definition for crowdsourcing. The developed definition reads “... a type of participative online activity in which an individual, an institution, a non-profit organization, or company proposes to a group of individuals of varying knowledge, heterogeneity, and number, via a flexible open call, the voluntary undertaking of a task.” (p. 195). Kahl et al. (2012) believe that developing more new technologies capable of collecting, communicating and disseminating individuals’ information on macro scales has led to more forms of crowdsourcing in organizational decision-making. Alam & Campbell (2016) state that crowdsourcing is part of a historically significant trend in which organizations target individuals, for value co-creation in completely new ways of Internet-based technologies.

The Crowdsourcing Framework defined by Liu (2014) uses the same traditional information-gathering six dimensions of why, who, what, when, where, and how to identify the interaction mechanisms that should be considered by designers of crowdsourcing systems. The “Why” dimension identifies the information requirement of a problem and the tasks needed from each crowd category. The “Who” dimension identifies the categories of crowd and matches the experience of each category to relevant required tasks. The “What” dimension identifies the interaction flows for engaging each crowd category in the process. The “When” dimension identifies the dynamic aspects of crowd categories interaction. The “Where” dimension identifies locations and geographical aspects of crowd categories, category activities, and scenario. The “How” dimension identifies the interfacing devices and applications with

crowd categories. Also, in the “Where” dimension, the geographically-oriented data could be provided using Location-Based Services (LBS).

Location-Based Services (LBS):

The LBS could be used to locate living entities or objects across telecommunication networks (Oh et al., 2019). Several technologies are utilized by LBS for knowing where an information device is geographically located. Examples of technologies used for LBS are the Global Positioning Satellites (GPS), Assisted Global Positioning Satellites (AGPS), Cell Identification (Cell ID), Broadband Satellite Network (BSN), Radio Frequency Identification (RFID), and Near-Field Communication (NFC).

Radio Frequency Identification (RFID)

The emerging technology of smart watches with embedded sensors to recognize objects and forearm gestures expands the use of such applications in full integration with RFID and NFC technologies. The RFID is a generic term for technologies that use radio waves to automatically identify entities, whatever inanimate, movable, or live. The entities are identified by information that may include a unique identifier or more data such as profile, transactions, measurements, account, weight, or birthdate (Garfinkel & Holtzman, 2006). The RFID has been identified as one of the ten greatest contributory technologies of the 21st century (Chao et al., 2007).

Near-Field Communication (NFC)

The NFC is a form of short-range wireless communication where the antenna used is much smaller than the wavelength of the carrier signal. NFC devices can be used as an identification label, master key, and a link for data transfer. As the NFC standard builds upon established standards of RFID technology, it enables devices to act both as a RFID tag as well as a reader of RFID tags (Kranz et al., 2013). By using the NFC along with wireless sensors and smartphone applications, data is collected from NFC enabled devices (Zhang & Li, 2011).

Remote Sensing

Remote sensing is a valuable source of spatial information, and its utility has been proven on many occasions of strategic decision-making (Kumar et al., 2014). Joyce et al. (2009) address the use of remote sensing as a rapid-response data source and present a number of data types and image processing techniques along with relevant satellite technologies.

Big-Data Analytics

Big-Data provides opportunities to find insights in new and emerging types of content to answer questions that were previously considered beyond the reach (Trelles et al 2011). The Big-Data Analytics is the way to harvest the available opportunities of Big-Data (IBM, 2015). Big-Data analytics is defined as “the systematic use of data and related business insights developed through applied analytical disciplines (e.g. statistical, contextual, quantitative, predictive, cognitive, other models) to drive fact-based decision-making for planning, management, measurement, and learning” (Cortada et al., 2012: p. 2).

Figure 2. Conceptual Design of ODSS

Baboo and Kumar (2013) present an overview of the next generation data warehouse architecture based on Big-Data for better business insights. The proposed architecture consists of three tiers, which are the extracting of Big-Data from multiple sources, storing and cleansing, and the analytical reporting. Within such architecture, a typical Big-Data processing framework relies on cluster computers with a high-performance computing platform. The data processing tasks are being deployed by running parallel programming tools on a large number of computing nodes. A single data processing task is split into many small tasks each of which is running on one or multiple computing nodes (Wu et al., 2014).

Che et al. (2013) review several attempts that have been made on exploiting massive parallel processing architectures for Big-Data Analytics. Google created a programming model named MapReduce (Dean & Ghemawat, 2010) that was supported by the Google File System GFS, which is a distributed file system where the data can be partitioned over thousands of nodes in clusters. The MapReduce framework allows users to define and run two functions, map and reduce, to process a large number of data entries in parallel within reasonable time frame.

Other big companies created the Apache's Hadoop MapReduce, which is an open-source version of Google's MapReduce framework. The Hadoop MapReduce uses the Hadoop Distributed File System (HDFS), which is an open source version of the Google's GFS. The Apache open-source community created HBase, which is an open-source version of Google's BigTable built on top of HDFS and Cassandra. Cassandra is an open-source version of Amazon's Dynamo. Apache Hive is an open source data warehouse system built on top of Hadoop for querying and analyzing files stored in HDFS using a simple query language called HiveQL (Cuzzocrea et al., 2011).

Hadoop has several competitor platforms. Some of the competitors improved on existing platforms, and others came up with a fresh system design. Google Cloud Platform analyzes Big-Data in the cloud with BigQuery, which is an SQL-like query runs against multi-terabyte datasets in seconds to give real-time insights about the data (Hashem et al., 2015).

DEVELOPING A FRAMEWORK FOR INTEGRATING BDT WITH ODSS

Simon (1960) presents a process model for decision-making and problem solving in four phases, which are (1) Intelligence, (2) Design, (3) Choice, and (4) Implementation. Based upon Simon's model, a generic conceptual design of ODSS has been updated to include emerging BDTs as illustrated in figure 2.

The conceptual design consists of four functional units, which are the Intelligence Unit including four modules, the Design Unit including four modules, the Choice Unit including four modules, and

the Integration & Display Unit including three modules. The updated unites and modules of the ODSS conceptual design are defined in the following items.

ODSS-1. Intelligence Unit: The information relevant to the decision situation is gathered and maintained by the intelligence unit all through the decision-making cycle. Information gathering is conducted on both strategic and operational levels (Chen et al. 2008). Data may need to be related to a larger intelligence picture using Big-Data Analytics. Data may cause the user to consider new operational concepts that require the intelligence to be interpreted in a new context. Evaluation and feedback are continuously performed during every other phase of the intelligence cycle. The main quality attributes of data collected at the unit are timeliness, relevancy, completeness, accuracy, usability (tailored to the specific needs), objectivity, availability (including appropriate security classification), and synchronization with associated operations. The unit ensures that both data and Big-Data is filtered and processed to relevant information that is timely accessible to the team members and other modules while still adhering to security standards. Security standards include the need-to-know principles. The updated structure of the Intelligence Unit includes four modules as defined in the following items.

1. **ODSS-1.1. Monitoring Module:** It supports the production, dissemination, and display of data. It consists of nodes that can create, receive, edit, transmit, and store video clips as well as images, graphics, voice, text data, and sensors signals. Data can be shared interactively among system subscribers on a point-to-point or multi-point basis with a “push-pull” capability. The data is delivered interactively in such a way that the module can support the subscribers with further clarification or direct interpretations. The module may include several technologies such as Location-Based Services (LBS), Radio Frequency Identification (RFID), Near-Field Communication (NFC), and Remote Sensing.
2. **ODSS-1.2. Data Science Module:** It allows specific access privileges to several categories of users and multiple applications of the system. However, the huge expansion in volume, variety and velocity of Big-Data, as discussed before, exceeds the capacities of traditional Relational Database and Data-warehousing technologies. The module includes several technologies and analytical methods such as Big-Data Analytics.
3. **ODSS-1.3. Communication Module:** This module is responsible for building and managing a network of distributed data sources. The coordination protocols between the ODSS and each one of these sources include type of contents, structure, format, updating times, security, and error control of data exchange. Some data of this module may be subject to Big-Data processing technologies.
4. **ODSS-1.4. Assumptions & Validation Module:** The first responsibility of this module is to fill gaps of data in the decision structure with best estimates (Byrne 2005). There are several techniques for assuming missing data including statistical distributions, regression, cross references, modeling, and simulation models. Big-Data Analytics can effectively fill the gaps of missing data by comparing and matching techniques. The second responsibility of the module is to conduct forecasting activities including meteorological forecasts and prediction of decision consequences (Fildes et al. 2006). The third responsibility of the module is to check the validity of data collected through the Intelligence Unit’s modules and deliver data reasoning (Hernandez & Stolfo 1998). There are several methods for testing validity of data including both simple cross checking and sophisticated statistical tools (Castano et al 2008).

ODSS-2. Design Unit: The main responsibility of the Design Unit is to develop enough alternatives for decision choices. Creativity in developing diversified alternatives is a key factor in decision-making. Specifications, course of actions, and planning of alternatives and possible switching from one alternative to another should be clearly formulated. The updated structure of the Design Unit includes four modules as defined in the following items.

1. **ODSS-2.1. Knowledge Management Module:** The module is responsible for dealing with both explicit and tacit knowledge. Explicit knowledge is documented and easy to be programmed into the system by its own analysts and acquired by the system through repeated use. Tacit knowledge, on the other hand, is built in human beings as mental models and technical experiences. The tacit knowledge is managed in the ODSS through a network of experts in different domains and protocols of communicating with them. Knowledge engineers in the module interview the domain experts and gather the information necessary for the system (Wang & Belardo, 2005). A variety of knowledge acquisition techniques are used to transfer tacit knowledge into explicit knowledge including interviewing, Delphi technique, brain storming, and modeling (Nevo & Chan, 2007). The module is in full coordination with the Data Science Module (ODSS-1.2) in the Intelligence Unit for Big-Data mining and extracting knowledge about behavior of individuals, groups, concepts, and objects.
2. **ODSS-2.2. Modeling & Simulation Module:** The first responsibility of this module is to develop and maintain the model-base of the ODSS. The module provides vehicles for estimating the possible outcomes of decision problems over a wide range of possible conditions. The second responsibility of the module is to represent decision makers' preferences, to incorporate qualitative factors in decision structure, to integrate all models related to the case in consideration, and to develop the complete decision structure. The model base contains both optimizing and satisficing or heuristics models (Barkhi et al., 2005). The ability to run individual or combined models or to construct new models makes the ODSS a powerful tool.
3. **ODSS-2.3. Artificial Intelligence Module:** The module is responsible for improving the effectiveness and efficiency of decision-making processes using several Artificial Intelligence & Expert Systems methods (Khalil et al. 2012). The module can help in providing multi-agent systems for real time support and simulated environments. The module can also help in developing and using Fuzzy Logic and Neural Networks models for supporting decisions in specific domains (Brynielsson, 2007).
4. **ODSS-2.4. Crowdsourcing Module:** In most decision contexts, public participation is an emerging, large-scale arena for Internet-mediated interaction that has implications for both informal and formal response (Liu, 2014). With a focus on persistent customers' communication as one form of interaction, the module follows how the emerging information pathways that result serving different functions (Palen & Liu 2007). Crowdsourcing is used in ODSS for several purposes, such as production development and configuration, product design, community reporting, community work, and open innovation (Randhawa et al., 2016). Crowdsourcing Typology technique is one of the tools used for measuring public group wisdom (Tripathi et al. 2014).

ODSS-3. Choice Unit: The Unit is responsible for developing a preferences structure of group decision makers (Limayem et al., 2006). Once the problem definition, objectives, and policy strategies are agreed upon among legitimate stakeholders, the criteria hierarchy and preferences structure are developed and used for ranking the alternatives and measuring the degree to which each objective is met. However, the measurable criteria may change with time (Frijda, 2005), which need Big-Data

Analytics. The criteria for making the decision are refined, expanded, and weighted by interactions between the decision makers and the decision analysts. The main measure of merits of the Choice Unit is the selection of best alternative at each phase of decision-making based upon well-defined criteria that accurately represent the group wisdom. The updated structure of the Choice Unit includes four modules as defined in the following items.

1. **ODSS-3.1. Groupware Module:** Several groupware technologies are used to integrate and incorporate the wisdom of decision makers in the choosing process (Adkins et al. 2002). Several functions are conducted in this module, including a “Road Map” of the partial judgments leading to the recommended decision.
2. **ODSS-3.2. AHP Module:** The analytic hierarchy process (AHP) is a mathematically rigorous, proven process for prioritization using pairwise comparison judgments (Saaty, 1982). The AHP is used in the ODSS for several purposes including:
 - a. Organizing the complexity of decision structure.
 - b. Determining the internal and total priorities of alternatives.
 - c. Forecasting about next move of actors.
 - d. Allocating resources in all modes of operation.
 - e. Selecting the most relevant cases to retrieve for investigation.
 - f. Integrating qualitative factors with quantitative factors in decision structure.
 - g. Evaluating the ethical responsibilities in inverse decision support cases (Kabil 2012).
3. **ODSS-3.3. Sensitivity Analysis Module:** The main responsibility of the module is to check the sensitivity of a decision to any changes may arise in decision parameters. Also, to check the validity of data received from the Assumptions & Validation Module (ODSS-1.4) of the Intelligence Unit to be incorporated in the decision structure. Sensitivity of the decision to assumed data is analyzed for deciding if the assumption is accepted or it needs further effort for validation.
4. **ODSS-3.4. Tasks Synchronization Module:** The module is responsible for monitoring, controlling and adjusting the pace of decision cycle over operational events. An E-Net based on Petri net-based formal model (Liu et al., 2015) is used for modeling and analyzing response timing and synchronization considering uncertain activity, execution duration, uncertain resource quantity, and uncertain duration of resource preparation.

ODSS-4. Integration & Display Unit: The unit is responsible for integrating all unites and modules of the ODSS and facilitating its team to access transparently the internal and external components of the system (Huang et al., 2002). The main objective is to provide everybody with the right information at the right time and in the right way. Incorporating an intelligent visualization module helps in providing at the time the relevant information that is necessary for the adequate behavior for fulfilling a specific task in specific situation. It also helps in providing the relevant information in the right way that promotes its rapid perception, proper understanding, and effective use. The main measure of merits of the Integration & Display Unit is to insure transparent seamless secure work of the ODSS all through the phases of decision-making process. The updated structure of the Integration & Display Unit includes three modules as defined in the following items.

1. **ODSS-4.1. Team Interface Module:** The main function of the Team Interface Module is to create and provide interface that minimizes the time of team comprehension. Shen-Hsieh and Schindler (2002) suggest approaches to use web-based interface technologies to create visual metaphors for data including visualizing time, collaborating, and modeling scenarios. They also demonstrate approaches to embedding more abstract constructs like decision theory,

statistical analysis, and competitive advantage into these interfaces. Bharati and Chaudhury (2004) discuss the quality of interface in web-based decision support systems. The module is also able to combine several displays in a single dynamic presentation and to supply the displays being generated with various interactive facilities such as zoom, pan, rotate, focus, query, mark, filter, or follow a hyperlink.

2. **ODSS-4.2. Visualization Module:** The module is responsible for effective preparation, organization, and representation of Big-Data in intelligent maps relevant to the goals and suitable to intended recipients considering the time pressure and stress factor (Andrienko & Andrienko, 2007). The intelligent maps help reducing the information load on the recipient, increasing the clarity of the information presentation, and allowing quick recognition of the meaning of the information conveyed.
3. **ODSS-4.3. Administration & Security Module:** The module is responsible for managing a role-based access control and security system. The system assigns and maintains the authority level depending on the situation and the needs, goals, and characteristics of the intended recipient. The needs depend, among others, on the role of the addressee in the decision-making situation. The module specifies the level of authority and type of access for each of the roles. An integrated security mechanism may be used to optimize security protocols and mechanisms of various heterogeneous networks in ODSS. One requirement of the integrated security mechanism is to interface with security protocols of open ubiquitous sensor networks. Such integration includes the support of mobility management, quality of service provision, and security interoperability.

CHECKING THE VALIDITY OF CONCEPTUAL DESIGN

The exercise suggested in this study for testing validity of the updated conceptual design of the ODSS is to recall the four perspectives of Balanced Scorecard (BSC) of organization strategic management as core requirements of ODSS (González, et. al, 2012). The administrative requirements of ODSS is adapted from (Kabil & Kabeil 2014). Based upon the definition of both core and administrative requirements, a model of Quality Function Deployment is developed to test the capability of the ODSS to provide these types of support.

The four perspectives of the BSC are the financial, customer, business processes, and learning and growth (Kaplan & Norton 1996). The BSC is used in several types of research for measuring and supporting organizational strategies (Mehralian et al. 2018; Gupta & Salter, 2018). The definition of both core and administrative requirements are listed in Table 1 with examples of their relative priorities using the Analytical Hierarchy Process (AHP). The table includes summary of requirements in 10 rows along with the Weight and Relative Weight Percent of each.

The evaluation of the conceptual design modules is based upon the use of Quality Function Deployment (QFD) technique. The set of ODSS Requirements and their priorities are used as inputs for the QFD model. The QFD is an overall concept that correlates design quality with user requirements (Sankaran et al., 2008). It has been used in several domains including decision support (Kabil & Kabeil, 2014; Kara-Zaitri & Al-Daihan, 2008; Simitsis & Vassiliadis, 2008). The technique uses matrices to collect, analyze and manage goals towards a final product. However, 95% of the studies applying QFD so far use only the first matrix, called House of Quality “HoQ” (Chan & Wu 2002). Basically, such matrix correlates requirements “what” to design modules “how”. The correlations between the requirements

Table 1. Priorities of ODSS Requirements

RN	% Rel. Weight	Weight (1-5)	Requirements
1	10.6%	5	Supporting financial aspects of the organization.
2	10.6%	5	Supporting customer's aspects of the organization.
3	10.6%	5	Supporting business processes aspects of the organization.
4	10.6%	5	Supporting learning and growth aspects of the organization.
5	10.6%	5	Rapidly deploying compatible information and communication systems to decision-making team.
6	8.5%	4	Calling for expert review of decision proposals.
7	8.5%	4	Locating an individual, facility, vehicle, or object on a map.
8	8.5%	4	Keeping historical Big-Data of the entire case for analysis and research.
9	10.6%	5	Insuring availability and security of the system
10	10.6%	5	System admin being able to setup and manage the system.
		47	Total Scores

and the design modules are specified using symbols of “strongly related,” “moderately related,” “weakly related,” or “not related,” which represent the corresponding numerical values 9, 3, 1, or 0 in the matrix calculations. The row score of design modules is the sum of the product between the relative weights of the integrated requirements and the correlations (between requirements and modules) as partially depicted in figure 3.

SOLUTIONS AND RECOMMENDATIONS

The output of the HoQ matrix is summarized in table 2. The relative weights (%) of the ODSS modules represent the percentage of the total score that each component contributes in the conceptual design.

Figure 3. Part of HoQ of the ODSS

Table 2. Relative weight percent of the ODSS modules

ODSS1.1	ODSS1.2	ODSS1.3	ODSS1.4	ODSS2.1	ODSS2.2	ODSS2.3	ODSS2.4	ODSS3.1	ODSS3.2	ODSS3.3	ODSS3.4	ODSS4.1	ODSS4.2	ODSS4.3
8.6	9.6	7.7	7.2	7.2	5.0	5.0	8.2	6.1	4.5	6.0	7.0	5.9	5.8	6.2

As the table indicates, the modules of the conceptual design support all requirements of ODSS. Each requirement is supported by a set of integrated modules in a balanced way. The modules of the highest contribution in the conceptual design are the modules most related to BDT. These modules are the Big-Data Science module (ODSS-1.2), the Monitoring module (ODSS-1.1), and the Crowdsourcing Module (ODSS-2.4).

The Implementation of Conceptual Design

The Basic modules of ODSS are developed as a conceptual design, which provides a general foundation for the detailed design and implementation of an application. The conceptual design provides a system that is flexible and responsive to decision makers' need in developing their own system. The initial stages of the implementation of ODSS consist of the establishment of facilities and staffs to carry out the basic functions of the system. Once an initial allocation of resources has been made, the functions of the system can be established in an operating condition. The major task in the development of the system involves integrating the various and widespread strategic information activities already existing in the organization with the new Big-Data activities.

FUTURE RESEARCH DIRECTIONS

There are three main avenues for future research on the same topic. First, to test empirically the validity of the adapted conceptual design of BDT in ODSS. Second, to test the applicability of the proposed theoretical models of adapted ODSS across several countries with different levels of infrastructures, ethics and cultures. The third avenue is to explore the user and organizational acceptance of the proposed model.

CONCLUSION

With the growing trend of global competitiveness and business complexity, the need arises for integrating BDTs in the design of ODSS (Jespersen, 2018; Garrido, 2015). BDTs enable ODSS to deal with data of volume, variety and velocity beyond the capability of traditional databases and data-warehouses in ODSS.

The basic modules of updated ODSS with BDT are presented as a conceptual design, which provides a general foundation for the detailed design and implementation of an application. The validation of the proposed conceptual design is conducted on a test-case based upon the BSC perspectives as well as requirements common for ODSS scenarios. The relative percentage of the total score that each module contributes in the conceptual design is evaluated using the Quality Function Deployment (QFD) technique. The results show that each requirement of the system is supported by a set of integrated modules

in a balanced way. The modules of the highest contribution in the conceptual design are the modules most related to BDT.

The conceptual design provides a system that is flexible and responsive to decision makers' need in developing their own ODSS. The initial stages of the implementation of the system are given. By combining the conceptual design with a test of internal validity and guidance of implementation, the study has provided some useful information to build upon.

KEY TERMS AND DEFINITIONS

Big-Data: The term “big data” is related to gathering and storing extra-large volume of structured, semi-structured and unstructured data with high Velocity and Variability to be used in advanced analytics applications.

Big-Data Analytics: Big data analytics is the process of examining large and varied data sets of big data to uncover information including hidden patterns and unknown correlations that can help organizations make better business decisions.

Big-Data Technology: There are several sources for big data including streaming data such as data from a web of connected devices and IoT. social media such as marketing, sales and support data, and publicly available sources such as the US government’s data.gov and the European Union Open Data Portal. These different sources need different technologies to deal with such as Apache Hadoop, Microsoft HDInsight, NoSQL, Hive, Sqoop, and PolyBase.

Crowdsourcing: Crowdsourcing is related to the act of collective intellectual gathering of information that comes from the public to be used in completing a business-related task.

Data Science: Data science is a multi-disciplinary field that follows scientific approaches, methods, and processes to extract knowledge and insights from structured, semi-structured and unstructured data.

Decision Support Systems: A decision support system (DSS) is an information processing system that supports decision-making activities. DSSs can be data-driven, model-driven, or a combination of both.

Organizational Decision Support Systems: Organizational decision support systems (ODSS) is a special type of DSS that focuses on organizational tasks affecting several organizational functions.

Data Mining for Fraud Detection

Roberto Marmo

Universita' Pavia, Italy

INTRODUCTION

The term fraud involves one or more people, they deliberately act secretly to take away some one valuable thing for their benefit. The statement fraud is as old as human being, it takes various forms. Because of expansion of modern technology, number and scenario of fraud are increasing dramatically. Reputation blemish and losses caused are primary motivations for technologies and methodologies for fraud detection. The Association of Certified Fraud Examiners (ACFE) estimates that 5% of revenue is lost to fraud and embezzlement every year. Applied to the U.S. GDP, this amounts to \$730 billion every year (<https://www.acfe.com/press-release.aspx?id=4294973129>).

Fraud detection is based on huge logged data sets, it involves: monitoring and tracking the behavior of users, constructing models and profiles of fraudulent behavior.

The problem is very difficult because fraudsters takes many different forms and they are adaptive, in order to avoid security measure.

Data mining refers to extracting knowledge from a mass of data, in order to acquire the rules that provide decision support and determine what action should be taken. Data mining techniques are usually applied to fraud detection, due to their great flexibility, adaptivity and speed.

The aim of this contribution is to describe data mining techniques for fraud detection, in order to achieve higher cost savings and legal evidence. Solutions and recommendations regarding automobile insurance, credit card, e-commerce, telecommunications and others are also discussed.

BACKGROUND

The Association of Certified Fraud Examiners ACFE defines fraud as: “The use of one’s occupation for personal enrichment through the deliberate misuse or misapplication of the employing organization’s resources or assets”. Therefore, a fraud is a criminal deception, use of false representations to obtain an unjust advantage, or to injure the rights and interests of another.

The main reason behind the commitment of fraud is to achieve gain on false ground by an illegal means. This has a dramatic impact on the economy, law and the human moral values.

There are different kinds of fraud: internal/occupational or external. Internal frauds happen when an employee commits fraud against his or her organization. External frauds involve a wide range of schemes, including vendors, customers or thefts by other third parties.

Frauds can be classified according to three areas:

- **Motive:** The main reason behind commit fraud;
- **Means:** The nature or form of the fraud involved to achieve the goal;
- **Methods:** The facilities and tools that are used to commit fraud.

DOI: 10.4018/978-1-7998-3473-1.ch079

Diversity of fraud regards organizations, governments, and individuals such as external parties, internal employees, customers, service providers and suppliers.

Each fraud area has its specific characteristics and faces different challenges, therefore it is important to analyze the fraud scenario in order to establish:

- What is a fraudulent behavior and modus operandi over time;
- What is a fraudulent person;
- Degree of available knowledge about known fraud;
- Quantity and type of available data.

Planning audit strategies is a posteriori fraud detection problem with prevention purpose of analyzing historical audit data and constructing models of planning effectively future audits. A case study is presented by Bonchi (1999) which illustrates how techniques based on classification can be used to support the task of planning audit strategies.

Implementing the right technology is the key factor in order to analyze and to prevent fraud. Fraud prevention and detection are the proper protection mechanism against fraud, but fraud prevention alone is not sufficient, fraud detection is required to protect vital services in business systems. Some of the major benefits of investing in fraud detection software include:

- Detecting and preventing loss;
- Tracking of vulnerable points in a system that can leave it open to fraudsters, such as lack of data on behavior of users;
- Efficiently safeguarding organizational, security, operational and financial data;
- Providing a sense of reliability in an organization that has succeeded in avoiding catastrophes in an environment, where fraud attacks can be expected due to risk factors and complexity.

Applying data mining to fraud detection is suitable to search for patterns indicative of fraud, as stated in next paragraphs of this chapter.

A common obstacle for predictive fraud detection models is the rare occurrence of the target event. The proportion of identified fraud cases in the model input data is usually very small, making it difficult to extract the fraud signal in the data.

It is difficult to provide estimates since some fraud may never be detected, and the operators are reluctant to reveal fraud losses, due to show an appearance of reliability and security in business operations, to avoid reputation blemish.

It is necessary to take into account cost of fraud detection and cost of fraudulent behavior, because stopping a fraud of few dollars can require a very expensive system. This is possible by introducing a decision layer on top level system, in order to decide the action taking into account factors, like the amount of transaction and the risk associated to user doing the transaction.

The development of new detections methods is more difficult, due to the severe limitation on privacy and on exchange of ideas due to confidentiality reasons. Moreover, data sets are not available and results are often not disclosed.

DATA MINING

Data mining is about finding insights which are statistically reliable, unknown previously, and actionable from data (Elkan, 2001). This kind of approach must be well-defined, cannot be solved by query and reporting tools, and guided by a data mining process model.

In particular contest of fraud detection, data mining analyzes the huge volumes of transactions and billing data and seeks out patterns, trends and clusters that reveal fraud.

Relevant technical problems are due to:

1. Imperfect data not collected for purpose of data mining, so they are inaccurate, incomplete, and irrelevant data attributes;
2. Highly skewed data, there are many more legitimate than fraudulent examples, so by predicting all examples to be non-fraud a very high success rate is achieved without detecting any fraud;
3. Higher chances of over fitting, that occurs when model high accuracy arises from fitting patterns in the training set that are not statistically reliable and not available in the score set.

The main steps for implementing fraud detection based on data mining regarding business organization are:

1. Analyze the fraud objectives and the potential fraudsters, in order to converting them into data mining Objectives;
2. Data collection plan, to collect clean data and maximize anti fraud impact;
3. Data cleaning and normalization;
4. Build a data mining model;
5. Use the model on data set to discover data relationships;
6. Segment data and drill down on the differences between actual and projected charges;
7. Pinpoint records that have a higher chance of being fraudulent;
8. Evaluation results in order to review the process;
9. Insert the model into the business data stream, in order to examine only the records that meet this selection Criterion;
10. Compare your subset to the entire data population, to examine the frequencies with which fraud appears.

Data mining approaches differ in the classes of problems they can solve, as follows.

- Classification builds up and utilizes a model to predict the categorical labels of unknown objects to distinguish between objects of different classes. These categorical labels are predefined, discrete and unordered. Examples: Neural Networks, CART, logistic regression.
- Clustering (also known as data segmentation or partitioning) is used to divide objects into conceptually meaningful groups (clusters), with the objects in a group being similar to one another but very dissimilar to the objects in other groups. Examples: Neural Networks, K-means, Kohonen, Factor analysis.
- Prediction estimates numeric and ordered future values based on the patterns of a data set. Examples: time series analysis.

- Outlier detection is employed to measure the distance between data objects to detect those objects that are grossly different from or inconsistent with the remaining data set.
- Regression is a statistical methodology used to reveal the relationship between one or more independent variables and a dependent variable. Examples: Neural Networks, CART, Regression, generalized linear model.
- Visualization refers to the easily understandable presentation of data and to methodology that converts complicated data characteristics into clear patterns, to allow users to view the complex patterns or relationships uncovered in the data. Example: bar charts, 3d charts, parallel coordinates.

In particular, typical detection approach consists in outlier detection where the non-fraudulent behavior is assumed as normal and identify outliers that fall far outside the expected range should be evaluated more closely. Many algorithms use concepts of proximity in order to find outliers based on their relationship to the rest of the data. However, most applications can contain hundreds of data dimensions, the data is sparse and the proximity becomes substantially more complex. creating the lack of all likely patterns needed to train suitable data mining models. This problem accentuates when the fraudulent patterns are not only scarce, they also change over time. Change in fraudulent pattern is because fraudsters continue to innovate novel ways to circumvent measures put in place to prevent fraud. Limited data and continuously changing patterns make learning significantly difficult. The work of (Porwal and Mukund, 2019) hypothesizes that good behavior does not change with time and data points representing good behavior have consistent spatial signature under different groupings. Based on this hypothesis, this paper proposes an approach that detects outliers in large data sets by assigning a consistency score to each data point using an ensemble of clustering methods, the main contribution is proposing a novel method that can detect outliers in large datasets and is robust to changing patterns.

Many fraud detection systems operate in this way: supervised approaches on labelled data, hybrid approaches on labelled data, semi-supervised approaches with legal (non-fraud) data, unsupervised approaches with unlabelled data (Phua, 2010).

In case of pattern recognition problem requiring great flexibility, adaptivity and speed, neural networks are suitable because they are inspired by the biological neural networks that constitute animal brains, might prove even more effective in rooting out e-commerce fraud (Weatherford, 2002). Unsupervised neural networks can mainly be used because they act on unlabelled data, in order to extract an efficient internal representation of the data distribution structure.

Fraudsters often involve a group of people who work together. To uncover these groups, organizations need to be able to extend the analysis beyond single accounts. Techniques like link analysis, association analysis, and path analysis can help to uncover relationships that point to suspicious behavior.

The relational approach (Kovalerchuk, 2000) is useful for discovering financial fraud, because overcome difficulties of traditional data mining in discovering patterns having only few relevant events in irrelevant data and insufficient statistics of relevant data.

Three classification algorithms and one hybrid meta-learning was introduced by Phua (2004), to process the sampled data partitions, combined with straightforward cost model to evaluate the classifiers, so the best mix of classifiers can be picked.

One relevant obstacle for using neural network techniques is the high diagnostic quality: since only one financial transaction in a thousand is invalid no prediction success less than 99.9% is acceptable (Jayasingh and Swain, 2011). Other disadvantages include greater computational burden, proneness to overfitting, the empirical nature of model development and black box nature, in the sense that while it

can approximate any function, studying its structure won't give you any insights on the structure of the function being approximated.

Visualization techniques are based on the human capacity in pattern recognition, in order to detect anomalies and are provided with real-time data. A machine-based detection method is static, the human visual system is dynamic and can easily adapt to the typical ever-changing techniques of the fraudsters. Visual data mining is a data mining approach that combine human detection and statistical analysis for greater computational capacity, is developed by building a user interface to manipulate the visual representation of data in fraud analysis.

Key fraud indicators (KFI) regard performance metrics like detection rate, false alarm rate, average time to detection after fraud starts, average number of fraud or minutes until detection. As first step, it is important to define a specific metric considering that misclassification costs can differ in each data set and can change over time. The false alarm rate is the percentage of legitimate that are incorrectly identified as fraudulent; fraud catching rate (or true positive rate or detection accuracy rate) is the percentage of transactions that are correctly identified as fraudulent; false negative rate is the percentage of transactions that are incorrectly identified as legitimate. The purpose of this kind of detection is to maximize correct fraud predictions and maintain incorrect predictions at an acceptable level. A realistic objective consists on balance of the performance criteria. A false negative error is usually costlier than a false positive error. Other important considerations regards: how fast the frauds can be detected and average time of detection, how many kind of fraud detected, on-line or off-line detection mode. A KFI is not only a financial indicator, and it might have no connection with finance. The way you set up a KFI is very different from the usual methods to set up a KPI (Key Performance Indicator, a measurable value that demonstrates how effectively a company is achieving key business objectives), because your needs are more complex and challenging.

CASE STUDY

Almost all technological system that involves money and services can be compromised by fraudulent acts. The works of Bolton (2002), Kou (2004), Ngai et al (2011), Abdallah (2016), Wells (2004) discuss a survey of different techniques and more details to detect frauds in some relevant applications. A taxonomy that combines research on patterns of observed fraud schemes with an appreciation of areas that benefit from data mining is discussed in Gray (2014).

The work of Lin (2015) discusses whether or not the suggestion of the experts agrees with the results obtained from adopting data mining techniques, this study uses both expert questionnaires and data mining techniques to sort out the different fraud factors and then rank the importance of them.

Automobile Insurance fraud

Insurance companies suffer due to dishonest insured claims, in many different types and sizes. Staged vehicle and rental car are the most prevalent fraudulent behavior. Real time support for detection challenge does not exist in this kind of fraud. Only a small portion of accidents participate in fraudulent cases, making them difficult to detect.

The work of Šubelj et al. (2011) discusses an expert system for detecting fraud using social network analysis for finding organized fraud groups. The system uses networks for representation of data, domain,

allowing formulation and analysis of complex relations between entities. Fraudulent entities are found by employing an assessment algorithm named Iterative Assessment Algorithm.

Visual analysis of insurance claims by the user helped discover the fraudster. NetMap (2004) is used to form groups of tightly connected data and to the capture of an actual elusive fraudster by visually analysing twelve months' worth of insurance claims.

Credit Card Fraud

As a result of the growing usage of credit card, fraudsters try to find more opportunities to commit frauds that can cause huge losses to card holders and banks. This kind of fraud takes many forms and categories (Laleh, 2009; Delamaire et al., 2009).

There are two class: a stolen credit card number is used for making a purchase that appears on account statement, the cardholders used a legitimate credit card but deliberately denies the transaction upon receiving the service because a dishonest merchant use the card without permission from the cardholders (Leung, 2004).

Offline fraud is committed by using a stolen physical card and the institution issuing the card can lock it before it is used in a fraud. Online fraud is committed via web or phone shopping because only credit card details are needed, a manual signature and card imprint are not required.

The work of Dorronsoro (1997) describes two characteristics: a very limited time span for decisions and huge amount of credit card operations to be processed that continue to grow in number.

Scalable techniques to analyse massive amounts of transaction data that efficiently compute fraud detectors in a timely manner is an important problem, especially for e-commerce (Chan, 1999).

Example of behavior feature: value and kind of purchases in a specific time, number of charges made from specific postal codes. Behavior analysis can also help uncover suspicious behaviors, such as a small gasoline purchase followed by an expensive purchase may indicate that someone was verifying that a charge card still worked before going after serious money. Departures from these norms may indicate fraud, especially in case of two or three such instances ought to attract investigation.

Machine learning techniques such as back-propagation neural networks and Bayesian networks are compared for reasoning under uncertainty (Maes, 2002) showing that Bayesian networks are more accurate and much faster to train but they are slower when applied to new instances.

E-payment systems with internal logics that are capable of detecting fraud transaction are more powerful when combined with standard network security schemes, so there is a well user acceptance of credit card as payment solution. The work of Leung (2004) issues on add-on module for detection in e-payment system, based on atomic transactions implemented in e-wallet accounts.

The strategy of detection by pattern recognition of user spending behavior is described in Chandola et al. (2009). The most frequently methods are the classification method, in specific neural networks techniques under supervised learning manner.

The work of (Pumsirirat, 2018) discusses a model of deep Auto-encoder and restricted Boltzmann machine (RBM) that can reconstruct normal transactions to find anomalies from normal patterns, an approach based on deep learning using Tensorflow library from Google.

Telecommunications Fraud

The fraud in telecommunications, as any transmission of voice or data across a communications network, regards the intent of fraudster to avoid or reduce legitimate call charges, so obtaining unbillable services,

acquire free access, reselling the services. Significant loss is in wireless and international calls, because they are most expensive, so when fraud is committed the costs mount quickly. In 2015 a telecom fraud association study estimated that the loss of revenue due to global telecom fraud was worth 38 billion US dollars per year (Sahin et al, 2017).

In this kind of application there are specific problems: callers are dissimilar, so calls that look like fraud for one account look like expected behavior for another, while all needles look the same. Sometime fraudsters create a new account without having the intention to pay for the used services. Moreover, fraud has to be found repeatedly, as fast as fraud calls are placed.

The work of Gossett and Hyland (1999) provides a classification of telecommunication systems fraud and grouped fraud into four categories:

- contractual fraud: using a service with no intention to pay;
- hacking fraud: breaching the systems of business and take advantage of available resources illegally;
- technical fraud: capitalizing on weaknesses exist in system technology;
- procedural fraud: attacks against the procedures implemented to reduce the risk of exposure to fraud, often attack the weaknesses in the business procedures.

The taxonomy proposed by Sahin (2017) differentiates the root causes, the vulnerabilities, the exploitation techniques, the fraud types and finally the way fraud benefits fraudsters. This work uses Caller NAME revenue share fraud as a concrete example to illustrate how taxonomy helps in better understanding this fraud and to mitigate it.

Due to legislation on privacy, the intentions of the mobile phone subscribers cannot be observed, but it is assumed that the intentions are reflected in the calling behavior and thus in the observed call data. The call data is subsequently used in describing behavioral patterns of users. Unfortunately, there is no specific sequence of communications that would be fraudulent with absolute certainty, because the same sequence of calls could as well be fraudulent or normal. Therefore, uncertainty in creating the model is needed. The calling activity of each mobile phone subscribers is recorded for billing in call records, which store attributes of calls like the identity of the subscriber, the number to call, time of the call, duration of the call, etc. Call data (or events input) are ordered in time, so it is possible to describe the daily usage formed by number and summed length of calls, and it is possible to separate them in sub-categories.

A common approach is to reduce the call records for an account to several statistics that are computed each period. For example, average call duration, longest call duration, and numbers of calls to specific countries might be computed over the past hour, several hours, day, or several days. Account summaries can be compared to thresholds each period, and an account whose summary exceeds a threshold can be queued to be analysed for fraud. The summaries that are monitored for fraud may be defined by subject matter experts,

It is possible to improve the threshold (Fawcett, 1996) using an innovative method for choosing account-specific thresholds rather than universal thresholds that apply to all accounts. This approach detection has several disadvantages: thresholds may need to vary with time of day, type of account, and type of call to be sensitive to fraud without setting off too many false alarms for legitimate traffic, so it is necessary periodically to review the setting by an expert to accommodate changing traffic patterns. Moreover, accounts with high calling rates or unusual, but legitimate, calling patterns may setting off more false alarms. These problems lead to expensive multiplying the number of thresholds.

An efficient solution must be tailored to each account's own activity, based on historic memory of the use, and must be able to learn the pattern on an account and adapt to legitimate changes in user behavior. It is possible to define the user signature, in order to track legitimate behavior for an user, based on variables and values described by a multivariate probability distribution. The disadvantage consists in estimating the full multivariate distribution.

Cahill (2002) describes an approach based on tracking calling behavior on an account over time and scoring calls according to the extent that they deviate from that pattern and resemble fraud; signatures avoid the discontinuities inherent in most threshold-based systems that ignore calls earlier than the current time period.

The cloning fraud is a superimposition fraud upon the legitimate usage of an account. The work of Fawcett (1997) describes a framework for automatically generating detectors for this cellular fraud, that is based on analysis of massive amounts of call data to determine patterns for a set of monitors watching behavior with respect to one discovered pattern. A monitor profiles each customer behavior and measures the extent to which current behavior is abnormal with respect to the monitor particular pattern. Each monitor output is provided to a neural network, which weights the values and issues an alarm when the combined evidence for fraud is strong enough.

The work of Ferreira et al. (2006) describes the problem of superimposed fraud, that is the fraudsters make an illegitimate use of a legitimate account and some abnormal usage is blurred into the characteristic usage of the account. The approach is based on signature that corresponds to a set of information, or vector of feature variables, that captures the typical behavior of legitimate user during a certain period of time. In case of an user deviates from typical signature a statistical distance is evaluated to detect anomalies and to send an alarm.

Concerning visualization methods, it is possible to create a graphical representation of quantities of calls between different subscribers in various geographical locations, in order to detect international calling fraud (Cox et al., 1997). As example, in a simple representation the nodes correspond to the subscribers and the lines from the nodes to the countries encode the total number of calls, so investigations on the brightly colored nodes revealed that some of them were involved in fraud. In this way it is possible to show a complete set of information and several tools on a dashboard to facilitate the evaluation process.

E-Commerce

As e-commerce develops rapidly, online auction is also becoming more popular, therefore several detection schemes are used (Aleem and Antwi-Boasiako, 2011)

In online auction, instantaneous support and detection is extremely important, so automatic procedure consists of two steps (Chang and Chang, 2014):

1. Construct features which extract user profiles and transaction histories of suspended accounts in order to discriminate between legitimate trader and fraudster;
2. Build a detection model based on these constructed features.
3. The work of Chiu et al. (2011) describes a feasible method to detect fraudulent accounts using social network analytical metrics and data mining approaches.

Adaptive Neuro-Fuzzy Inference System, which is a hybrid of neural networks along with fuzzy inference, can adapt to newer instances of fraudulent transactions (Shaji and Panchal, 2017).

The work of (Carta et al, 2019) proposes a novel data intelligence technique based on a Prudential Multiple Consensus model which combines the effectiveness of several state-of-the-art classification algorithms by adopting a twofold criterion, probabilistic and majority based, the goal is to maximize the effectiveness of the model in detecting fraudulent transactions regardless the presence of any data imbalance.

Other Case Studies

Bayesian networks can uncover simulated anthrax attacks from real emergency department data (Wong et al 2003).

The work of Cabral et al. (2009) presents two computational system for fraud detection for voltage electrical energy consumers, based on Self-Organizing Maps and a hybrid of data mining techniques, so electrical energy companies will better direct its inspections to avoid commercial losses.

Click fraud regards the deliberate clicking on advertisements (ads fraud) with no real interest on the product or service offered, it is one of the most daunting problems in online advertising. The book of Zhu et al. (2017) systematically review methods and techniques to prevent and defeat such fraud. The authors categorize such fraud into three categories: placement, traffic, action.

FUTURE RESEARCH DIRECTIONS

The available statistical models are unable to detect new types of fraud as they occur, because they must be aware of fraud methods such making a prevention effort, based on amounts of historical data, that can be implemented before the fraud occurred producing. Unfortunately, preventing fraud is an evolving and dynamic process and fraudsters create new schemes daily, thus making not suitable this static solution.

Future research is based on dynamic, self-correcting and self-adaptation in order to maintain continuous accuracy and adapt to identify and predict new scenarios to detect fraudulent activities as they occur. Relevant challenges consist on information silos, disparate systems and departmental processes that create information leakages.

Moreover, a useful feature is due to detailed results including the reason for suspicion of fraud, so the user can establish the priority of the suspicious transaction and its remedy.

CONCLUSION

Fraud cases have increased in recent years, particularly in business areas. The forms and styles of fraud are changing regularly. Thus, one big challenge regards coming up with algorithms that can learn to recognize a great variety of fraud scenarios, quickly enough to detect fraudulent activities as they occur.

The suggested strategy based on data mining consists in monitoring the behavior of users and analysis of contextual information, in case of this approach is applied on a specific problem with a-priori analysis of the problem domain and a specific choice of performance metric.

KEY TERMS AND DEFINITIONS

ACFE: World's largest anti-fraud organization and premier provider of anti-fraud training education and certification, web site <http://www.acfe.com>.

Data Mining: Finding insights which are statistically reliable, unknown previously, and actionable from data.

Financial Statement Audit: The examination of an entity's financial statements and accompanying disclosures by an independent auditor.

Fraud: A fraud is a criminal deception, use of false representations to obtain an unjust advantage, or to injure the rights and interests of another.

Fraud Detection: An automatic system based on description of user behavior and fraud scenario, in order to detect a fraudulent activity as soon as possible to reduce loss.

Fraudster: A person who commits fraud, especially in business dealings.

Art Innovative Systems for Value Tagging

INTRODUCTION

Consumers entering the art market are faced with an environment that gives them a vast number of options, but a limited amount of useful knowledge. While data on the current market are widely available, the necessary context to understand this ecosystem is much harder to effectively obtain. How can consumers know what artworks are good purchases without hiring an external consultant or conducting extensive research on their own? How can artists set the ideal price for their work, when this price is driven by numerous outside factors?

Today, artwork evaluations are conducted by human experts. Collectors with high budgets may hire highly priced art consultants and dealers to select artworks for them. For other buyers and sellers some online services exist, and they tend to rely heavily on extensive datasets of past sales. With these services, either the artists themselves or hired experts find comparable works and use these to determine a market price. These comparables are similar works that have already been sold and can be used to provide a basis for pricing. However, using these services can be time-consuming and expensive.

The art market is a unique problem area for modeling prices. Artworks are unique and their prices are driven by aesthetic and emotional considerations, as well as simple financial ones. Artworks seldom follow traditional economic models and need to be considered differently (Beckert, 2013; Velthuis, 2005). An artist seeking information on pricing his/her own artworks is faced with a challenging task. Gallerists sometimes recommend prices based on their own personal market experiences or on their professional contacts. Sometimes, these judgements are highly subjective and are based on emotional considerations about what price the work should be to fit with the narrative that the price is conveying to a buyer (Velthuis, 2005).

The nature of the art market has changed significantly since the 1940s becoming an “unpredictable financial roller coaster” (Shnayerson, 2019). Artists or art galleries have become brands, where buyers use the brands as a guarantee for quality (Pendergast, 2014). That creates a situation which restricts the number of participants on the top level as well as conditions where the phenomenon of promotion plays a crucial role in the artist’s success. In the reality of the 21st century art market, there are no longer artists who try to hide themselves from the social aspect of their artistic careers. The numerous artist accounts on Instagram and Facebook are clear examples of this statement. Artists, art galleries, and art dealers provide significant information to the Internet to increase an artist’s popularity. Active and established artists have personal websites and Wikipedia pages. If an artist does not have a Wikipedia page with many references, he/she is not considered an established artist. Galleries often create the promotion for

DOI: 10.4018/978-1-7998-3473-1.ch080

emerging artists. It is almost impossible for an established artist today to not have a considerable amount of information on the Internet. Emerging artists often try to follow the same strategy to provide as much as possible about their art and themselves.

The complexity of the market is exacerbated by the role of “superstars” (McAndrew, 2017). Consumers looking to reduce the amount of work that they must do to find a quality piece of art look for artists with well-known names and established reputations. This concentrates sales in a very small subset of artists and raises their prices accordingly.

An artist may experiment with using the Internet as a resource to help him/her determine a price for his/her artwork. However, while the amount of information available is vast, sifting through that information to find a comparable work is much more of a challenge. This can create problems for artists, who may overprice their work and lose sales, or underprice their work and diminish their market potential. Artists must take care to ensure that their prices are appropriate to the current stage of their career, so that they can fit into their role in the current market (Velthuis, 2005). Being perceived as too concerned with making money on artworks can be a significant hindrance to an artist’s career (Velthuis, 2005). In contrast, pricing too low can make an artist’s work less appealing from an investment perspective.

Past research on combining fine art with modern computing technology has been limited. Several works have addressed problems such as identifying the style, artist, or artistic period of a work based on its visual characteristics. Other works have used consumer data to identify which artworks a given user will interact with or purchase (He, Fang, Wang, & McAuley, 2016; Messina, Dominguez, Parra, Tratter, & Soto, 2018). However, integrating artworks into the broader context of the art market itself has been largely neglected by researchers.

This article will discuss the problem area of the art market, review a selection of past works that address developing recommender systems for artwork, and propose a design for a recommender system that will provide prices for a given artwork. The system is called ArtIST, which stands for Art Innovative Systems in Value Tagging.

BACKGROUND

The global art market plays a significant role in the international economy. The global art market was valued at 63.7 billion USD in 2017 (Freeman, 2018). Online sales are becoming increasingly significant, with over 29% of today’s gallery sales being made online (ArtTactic, 2018). Additionally, galleries are closing at a significant rate; more art galleries closed their doors in 2018 than opened them (Freeman, 2018). In the online market, consumers, especially newer consumers, are uncertain about making large purchases, due to their concerns about price instability (ArtTactic, 2018). The role of artworks as a means of investment must also be considered. Contemporary and Post-War Art were found in 2018 to have gains since 2000 on a par with the S&P 500 (Artprice.com, 2018).

The concept of automatic classification of artworks has received a large amount of attention in recent years. Identifying specific artists or artistic periods by developing features is a notable trend that has been addressed in several works (Falomir, Museros, Sanz, & Gonzalez-Abril, 2018; Gultepe, Edward. Conturo, & Makrehchi, 2018). Other researchers are exploring the idea of tagging based on other types of features, such as retrieving photographs according to their emotional content (Machajdik & Hanbury, 2010). Still, further work has been done on developing systems that allow images to be retrieved based on specific artistic concepts (Yelizaveta, Chua Tat-Seng, & Irina, 2005).

Artworks are unique in their role in the marketplace. They are not only valued as financial instruments, although they are comparable to more traditional instruments for investment in returns (Artprice.com, 2018), but for their aesthetic and cultural value. Over 40% of the collectors who were surveyed could not value their art collections (Freeman, 2018). Collectors make purchases for different reasons and behave differently when they are faced with market forces pushing them to buy or sell (Lovo & Spaenjers, 2018). This creates problems for consumers who want to understand the value of their purchases. Simple metrics, such as price lists, do not provide the context which is needed for consumers to understand the reasoning behind prices (Coslor, 2016). This creates tension between art buyers, who are armed with context-free price lists, and dealers, who are more accustomed to the nuances of the marketplace.

While developing recommender systems for prices has not received significant attention, several past authors explored the challenge of recommending works of art to users. In Messina et al.'s (2018) study, the authors use a dataset of past purchases to recommend artworks to a user that he/she is likely to purchase. These authors used features they derived from the manually provided artwork tags and the visual attributes of the work. Predicting which artworks a user would interact with on an artwork sharing site was a research question in He et al.'s study (2016). These researchers integrated the social relationships between artists as well as visual and temporal features into their model (He et al., 2016). Other works in the area of automated artwork recommendation include Saleh and Elgammal's (2015) study, in which the researchers attempted to classify works of art based on style and genre and predict the artist. They used this to recommend artworks such as a past work which was selected to a user.

Pawlowski (2019) developed a recommender system that could predict prices for works of contemporary art. The author trained the model on a sample of 20,543 popular paintings and used a set of features to derive recommendations. The researcher constructed the dataset by scraping an art sales site, and, by extracting features from the artist, provided text and the uploaded images. This project used features such as the area of the work, the artist's highest degree, the number of exhibitions the artist held, the number of comments, the brightness of the image, the blurriness of the image, and the dominant color of the work. In this work, the researcher concluded that the features that indicate the amount of time an artist spends on the art, such as its size, the popularity of the work and the artist's reputation are the most crucial toward determining the price.

FOCUS OF THE ARTICLE

This section proposes a design for the ArtIST system, which will utilize the same information that would be sent to a price consulting company to predict the price using big data analytics. The system has several main components. This section will explain the different components of the system and the rationale for their use. This section will also address the dataset that has been constructed to be used in the system as well as the features for it. Some features have already been developed, and they will be discussed here, as will other features that are currently being designed and tested. This provides an overview, but Powell, Gelich and Ras's (2019) research provides more details on the dataset and the features discussed in this work.

Overview of the ArtIST System

While artwork classification and recommendation have received some attention, the role of price prediction is largely handled by human experts. MutualArt ("MutualArt," 2019) has an extensive database

of past sales which its experts use to appraise new works. Another price advising tool can be found on FindArtInfo ("FindArtInfo," 2019). They also have an extensive dataset. Artists can use this to find other works like their own to use as a basis for their prices. Suggestions for how to price artworks can be found on a number of Web sites. An alternative method is that artists can also submit their works to professional appraisers. These can charge several hundred dollars for a consultation, which may place them out of reach for an artist early in his/her career. The challenge of pricing work is significant for artists without proven sales records.

ArtIST is a knowledge-based recommender system. Knowledge-based systems, in contrast to other types of recommender systems, are especially useful when they are applied to areas with high value items that have many characteristics and are purchased infrequently (Aggarwal, 2016). Consumers making artwork purchases have many different factors to weigh and may have very explicit requirements. The use of domain knowledge makes knowledge-based recommender systems a good fit for this application area.

The authors used Web scraping to extract the primary dataset for the ArtIST system. There are many Web sites that allow artists to post their work. They selected Artfinder.com to construct the current iteration of the ArtIST system (Artfinder, 2019). This site was a good fit for this project, due to the broad variety of mediums and styles which were showcased, as well as the large number of artists and nationalities that were represented. At the time of the writing of this article, the dataset has approximately 197,000 artworks, from over 2,700 artists in over 70 countries. The prices range from less than 20 USD to a million USD. However, it is notable that works most of the works are valued by their creators at less than 1000 USD. Most of the works that are bought and sold online are valued at less than 1,500 USD (Fischer, 2015). The works discussed here are targeted more toward casual art consumers rather than the higher end art collectors.

The system is built to recommend prices for specific platforms based on other artworks on that sales platform. The current system uses Artfinder.com, however, by expanding the dataset recommendations could be developed for other sales platforms. Different art websites and galleries may sell the same work for different prices. The results are personalized to the sales website or marketplace which the user is considering.

ArtIST Features

This dataset consists of a number of features that can be directly used for prediction or developed into other features. All artists on Artfinder have an about page where they may provide biographical information. Information can consist in, for example, the number of works that are currently posted on Artfinder and the artist's current country. It may also include details about their education, awards, and events that they have held. An artist's reputation is a key part of making a consumer feel comfortable in their purchase (Beckert, 2013). On their artist pages, artists also often provide links to their social media accounts. Social media are very widely used, with approximately 86% having Facebook accounts, 41% with Twitter accounts, and 56% with Instagram accounts. Instagram is very popular in the art world and among art buyers under 35 more than 75% of those surveyed use it to discover and keep up with artists (ArtTactic, 2018). Whether an artist had a social media presence listed was tested as a predictive feature. However, it had little value, possibly due to the high usage.

Additionally, a number of artists on Artfinder have reviews of their work listed by their past customers. However, these reviews are not particularly effective as a feature. Artists acquire reviews over the course of their time on the site. Approximately 50% of artists who are represented in the dataset do not have any reviews. Few artists have negative reviews, making the star ratings of an artist of limited value

as price predictive features. It is possible that, by utilizing sentiment analysis or other text processing tools, useful features could be extracted from the reviews.

An artwork also has multiple pieces of information provided on its page. All works have at least one image as well as a title. Many works provide short textual descriptions of the artwork. Additionally, artists tag their works to make them easier to find in the search engine. Works can be tagged with styles, mediums, subjects, as well as sizes. The artwork pricing model was developed using this same set of features.

How artists present themselves to their customer base can be used as a price predicting feature. This is explained by the important role that an artist's reputation plays in assuring consumers that his/her works have value. This work will discuss some of the features that have been developed for ArtIST below.

When testing features for the ArtIST system, the authors used a subset of 150,000 records to construct models. They used Orange (Demšar, 2013) for the testing. First, a model is built using the base set of features. The model chosen is random forest, and 100 trees are used. Then, a model is created using the new feature as an extension to the base set of features. The two models are then tested using 10-fold cross validation and their accuracy is compared. Often, multiple new features are tested together as extensions to the base dataset, so that their overall impact on the accuracy of the classifier can be assessed.

The base set of features that is used for these comparisons includes: The artist's unique username, which may or may not be their legal name; the medium of the artwork, which is tagged by the artist for the search engine of Web site; the style of said artwork, which is similarly tagged; the subject of that artwork, which is also tagged by the artist; the number of reviews that artist has, the percentage of five, four, three, two, and one star reviews that the artist has earned; the width of the artwork in inches; the height of the artwork in inches; the artist's current county; the artist's method of authenticating the work, which is whether or not the work is signed.

Table 1 shows a confusion matrix of a random forest model with 100 trees trained 150,000 records using only the base feature set. All prices are in USD and each price level is represented by a letter: A = (0 - 105), B = (105 - 205), C = (205 - 405), D = (405 - 605), E = (605 - 810), F = (810 - 1030), G = (1030 - 1445), H = (1445 - 1825), I = (1825 - 2455), J = (2455 - 3855), K = (3855 - 5000), L = (5000

Table 1. Confusion matrix with base features

M	5	4	17	13	9	3	11	6	11	48	9	109	156

- 10000), and M = (10000 +). The number of works actual at the listed price is represented by the rows and the predictions by the columns.

For example, the word count of artwork descriptions, artwork titles, and artist biographies is one of the simplest features that has been tested for effectiveness in price classification in the system. When it is used as an extension to the dataset, the word counts have value as price predictive features. One possible reason for this is that a lengthier biography is representative of a more experienced, and therefore higher, priced artist. Interestingly, the highest priced works often had the shortest artwork descriptions. The lack of extensive descriptions may due to the very dominating nature of the artwork photograph.

The authors also used whether the artist had a Facebook, Twitter or Instagram page listed on their profile as a feature. These features were of limited value alone. However, when combined with other features they improved the accuracy of the classifier. The large percentage of artists that have social media links posted may be the reason that it is not particularly useful as a predictive feature alone.

The authors tested the overall sentiment of the biography, artwork title and artwork description using VADER (Hutto & Gilbert, 2015). The text was largely neutral. The authors detected very little negativity in any of the analyzed text. However, the presence of positive sentiment had a place as a feature that could predict the price of a work.

Paragraph Vector, which was developed by Le and Mikolov (2014), was used by the authors to cluster biographies, education paragraphs, award information, and past events, as well as the artwork descriptions and titles. This was meant to place artists that had similar written content together. Ideally, artists with similar biographical information would have been placed in the same cluster. This clustering method was tested on a sample of the dataset with 150,000 records. The clustering of the biography, awards, education, or events section had a positive impact on the accuracy of the resulting classifier.

These features had some success in predicting the prices for works of art. With the addition of these features, the prices of artworks could be predicted with a precision of 0.685 and a recall of 0.69. However, more features will be needed, in order to develop a predictive system. New features must be constructed to fully take advantage of the value that the biography of an artist has in understanding his/her reputation.

Table 2. Confusion Matrix with word counts, social media, sentiment and text clustering features

	A	B	C	D	E	F	G	H	I	J	K	L	M
A	29617	3485	568	26	8	1	0	0	0	2	0	0	0

M	8	4	26	9	7	2	17	2	6	33	9	122	156

Table 2 is a confusion matrix that was developed using the experimental features discussed above as an extension to the base feature set.

The authors are developing features derived from the image of the artwork. These features include the percentage of edges in the work, the dominant colors of the work, and the lines and edges of the work. Developing visual features that can indicate the price is a very notable challenge.

Proposed Design of ArtIST

The current design for the system is two-tiered. It relies on the idea that artists who are at different places in their careers and with different styles will naturally price their work differently and be attractive to different buyers.

When a new artist is added to the system, he/she will be placed in one of the several clusters. These clusters will hold artists that are at similar career stages and ideally have similar methods of pricing their work. An artist will be placed based on the features of his/her career information as well as information about the types of work that he/she produces.

For example, an artist who is at a late stage in his/her career and primarily creates large watercolor landscapes which are sold for high prices should not be in the same cluster with an artist that is just beginning his/her career and primarily creates small, inexpensive, acrylic, and abstract works.

The features that will be used for this clustering will include features such as the artist's education level, information about his/her current country, his/her social media presence, and information extracted from his/her biography. Attributes of an artist's background, such as whether they attended art school or how many events, they have participated in may be used as a measure of an artist's career.

The ArtIST system will use the artists' collected works in a cluster to train a classifier. As this classifier was built for artists in that specific cluster, it will provide a level of personalization for the system. The classifier will use features specific to the work itself, such as the title, description, tags, and information derived from a photograph of the artwork.

This will help with addressing differences in prices that appear among works that are visually quite similar but were created by artists at vastly different stages of their careers. These features will be created based on the image, the textual description of the work, and its title and tags.

SOLUTIONS AND RECOMMENDATIONS

One of the most problematic aspects of developing this system is the task of clustering artists. Judging the state of an artist's career is a challenge even for an expert. The value of an artist's works can be influenced by factors such as what museums and notable collectors have acquired his/her work. The amount of deep domain knowledge which is needed to project the impact of thousands of different art education institutions, awards, art events, and collectors is truly staggering.

Developing a truly accurate means to find similar artists will require extensive collaboration with domain experts from different perspectives and backgrounds. Is it possible, for example, to place different art institutions into tiers of prestige? Does the style that the artist uses alter the impact on his/her reputation that participating in a particular show provides? Does time need to be a factor? If, for example, a museum suddenly dropped in quality, how that would impact the assessed value of the artists whose work it holds? In order to answer these types of questions, experts' advice is necessary.

One possible solution for this issue is developing a set of metrics, similar to the impact factor, which is used for the writing of academic papers, to assess the “impact” of representation in collections and at events. This allows for a more direct comparison between different classes of events. While those inside the art market can say that one art show is more influential than another, this information is largely hidden to the common art buyer.

Additionally, relevant features must be developed for classifying artworks. These must go beyond simple meta tags of subject and style but represent the work on a more complex level. While the mechanics of extracting low-level features, such as color, has been extensively researched, capturing the emotional resonance of a work of art is a challenge that must be addressed by computer scientists and artists together.

How can the aesthetic characteristics of a work be captured as features? One possible method of representing an artwork is to attempt to capture the emotional qualities of a work using visual features. For example, the psychological impact of color on emotion has been researched extensively but creating a direct link between a specific emotion and the percentage of the work that is painted a specific hue of orange with a specific level of saturation and particular value is not as directly linked to emotion. This also requires a link between specific emotions and the sales value of a work. Do specific emotions make a consumer more or less likely to want to make a purchase?

FUTURE RESEARCH DIRECTIONS

The integration of technology with both the artworks themselves and the broader context of the art market is an increasingly notable area of research. If current trends continue, online art sales will have an increasingly prominent role in the global art market. This will demand the development of tools that can make the experience of purchasing artworks online simpler and less uncertain for users.

Recommender systems in the context of artwork have received much less attention. With the considerable size of the investments that consumers make in their artworks, this creates an opportunity to be explored by later researchers.

For this research, the next phase will be the construction and testing of the ArtIST system. This will require the development and testing of more features for both stages. The clustering of artists must have new features added to make the clusters useful. Ideally, the clusters should be descriptive.

Additionally, features describing the artwork must be improved, so that a distinction can be drawn between artists within the same cluster, but with different values.

Finally, the addition of data from other sales platforms would allow models to be built that were customized for those platforms. While the accuracy of the models on Artfinder is high, the addition of data from a greater variety of sources would permit the development of a more personalized system.

CONCLUSION

It is not enough to merely consider a work of art in a vacuum. Artworks exist in a complex environment, and their prices reflect this fact. The reputation of their creating artist, the level of innovation of the work, its aesthetic power, and its investment potential influence one another to provide a price for a work of art.

This demands the development of a system that can integrate this domain knowledge to provide artists, buyers, and dealers with a means to navigate the complexity of the market. Simple lists of past sale

prices are not enough to allow artists and buyers for informed decisions. Artists must be able to price their works to best appeal to new skeptical online buyers.

The current environment provides human experts. However, these are often expensive, and may take days to come to a conclusion about the price for an artwork. Online lists of prices from past auctions do not provide sufficient context for an artist to make an educated decision about the price for his/her work. Prices in the art market are highly personal.

This work discusses one possible design for a knowledge-based recommender system that could address this issue. The system will not require large amounts of information about an artist but will utilize what an artist would provide to a comparable human based system. The use of biographical information, photographs of the work, and tags as features make the system accessible for an artist.

KEY TERMS AND DEFINITIONS

Classifier: A model that can be used to place objects into discrete categories based on some set of features. Classifiers are trained on datasets.

Confusion Matrix: A table that represents the error rate of a classifier.

Contemporary Art Market: In the context of this work, the contemporary art market consists of artists, art dealers, art collectors or other buyers working in or near the present day.

Emerging Artist: An emerging artist is an artist that has had some professional development as an artist. However, they are not widely recognized and are not at the potential height of their career.

Established Artist: An established artist is an artist that has a solid reputation as an artist among art critics, art buyers, galleries, and other stakeholders in the art world. They generally can sustain themselves through their art and are represented by leading art galleries and art museums.

Feature: An attribute or characteristic of an object that can be used to develop a classifier.

Knowledge-Based System: A recommender system that uses knowledge of the application area to make suggestions to users. The recommendations use domain knowledge to offer recommendations that fulfill the constraints provided by the user.

Primary Art Market: Works of art that are being sold by either the original artist or a direct intermediary. This is in contrast to the secondary art market which consists of artworks that are being sold by collectors or other purchasers.

Recommender System: A system that aids in decision making by providing users with suggestions. These suggestions are developed based on past information or domain knowledge.

INTRODUCTION

Information Systems (IS) are today an integral part of the functioning of public administrations and bodies, the activity of businesses and the way of life of citizens. The security of these information systems has become a major issue for all public or private sectors, which would be very strongly affected in the event of serious malfunctions (T. R Peltier, 2016).

Information security policy is the general term used to describe any document that transmits an element of the security program in order to ensure compliance with the organization's security goals and objectives. Since this definition covers a wide range of security policy documents, it is useful to describe the various types of information security policies that an organization may use. The terms used below to describe these types of information security policies are generally used in the information security industry and will be used consistently throughout this paper (Ifinedo, 2014). However, it is not unusual for a government organization or agency to have different names for the same types of information security policies. For example, in many organizations and certainly in government departments, the word "policy" is closely associated with laws and regulations (Rees, Bandyopadhyay, & Spafford, 2003). In these cases, a limited number of individuals (e.g., the legislature) have the power to create a policy, so that an information security policy is generally referred to by other names such as "information security statement", or "information security document" or other terms avoiding the use of the word "policy". The term used by an organization to describe these documents is irrelevant. The overall organization and completeness of these documents are important (Hong, Chi, Chao, & Tang, 2006).

The Information Systems Security Policy (ISSP) reflects the expectations and requirements of the Executive Management with regard to the Information System (Canavan, 2003; Höne & Eloff, 2002b) (Canavan, 2003). It must take into account at least the needs in terms of availability, confidentiality and integrity of applications and data used and transiting on networks and systems. It consolidates a set of technical, organizational, legal and human security rules and principles to ensure an efficient and uniform level of security (Fomin, 2008). The ISSP is the counterpart of the Information Systems Master Plan for security. It can lead to an ISSP action plan that prioritizes projects to meet ISSP objectives. The objectives of the Information Systems Security Policy (ISSP) are described in figure 1.

DOI: 10.4018/978-1-7998-3473-1.ch081

Figure 1. Information system security policy objectives

There are several standards and best practice guidelines to assist organizations in implementing an information systems security policy such as ISO 27000, ISACA, NIST, etc. ISO 27001 (ISECT, 2012) is an international standard that is part of the ISO 27000 family of standards (Von Solms, 2005). It refers to a set of standards relating to the information security management system. The ISO 27001 standard is a British standard that came into being in October 2005, succeeding in the BS 7799-2 standard. It describes the requirements for the implementation of an Information Security Management System as shown in figure 1. This standard allows companies to choose security measures to ensure the protection of sensitive assets within a well-defined perimeter by implementing a systematic and proactive approach to security risk management.

Best practice guides such as ISO 27001, COBIT, ISACA do not provide the practical framework for implementing an IS security policy (Höne & Eloff, 2002a). The objective is to guide organizations in their approach to implementing an IS Security Policy through a practical guide to implementing an IS Security Policy.

Problem Statement

Many prescriptive approaches to ISO 27001 already exist, for example, ISO 27003, which is the official standard with guidelines for ISO 27001 (Talib, M. A., El Barachi, M., Khelifi, A., & Ormandjieva, 2012). Several steps to implement the management framework provided in ISO 27001, called information security management system ISMS, are presented. However, a practical methodology for implementing an information security policy does not exist.

Figure 2. A brief history of ISO/IEC 27001

Many organizations do not have the resources or expertise to conduct a risk analysis and implement an ISMS (Mintzberg, H., Lampel, J., & Quinn, 2003). Therefore, they could now know what aspects of security might be relevant to them. Instead of doing a comprehensive risk analysis, an organization could also look to its peers. What are they doing? Although it is not as good to follow your peers as it is to do an extensive risk analysis, it is certainly better than setting up controls for no reason.

Modern times require different approaches to problems. Nowadays, mobile phones and tablets are common products. Employees are supposed to work everywhere. Information is quickly shared via social media. How do companies manage these new issues - what controls do they put in place and how do they select them?

To date, there was no literature on practical research using ISO 27001. Almost all the results had a very limited number of references. However, some were still useful.

There are very few scientific papers on ISO 27001, and none found that research practice uses ISO 27001 controls as described in the background section. This paper can be considered exploratory: The data collected in this research may well be used to formulate hypotheses for other research projects.

Research Question/Approach

The research question in this work is: What relevant ISO 27001 controls and good practices do corporate information security managers choose to implement, and why are they chosen?

The approach taken in this research is qualitative research, using interviews with experts. Expert interviews are a good way to explore an area of research. Experts often know a lot about the research topic. By talking to several of them, it is possible to know whether there is a consensus or whether there is still much debate on certain subjects. Both results could be used in future research.

Unlike quantitative research, qualitative research is used to focus more on “why” and “how” questions. As a result, qualitative research generally takes smaller, but more focused samples than quantitative research. Qualitative research often does not have a clear hypothesis in advance. Instead, we need an open question. The selection is not made by statistical chance, but according to what is available. When

interviewing information security officials, the objective is to get an overview of the controls they choose and why they have been chosen over others.

Purpose

As there is very little scientific literature on the practical use of ISO 27001, this research can be used as exploratory research. The purpose of this paper is to investigate what controls are commonly used and how they are selected to the implementation of an information security in large public organizations in the Middle East and North Africa MENA through ISO 27001 (Calder, A., & Watkins, 2010), with a specific focus on practical framework for the implementation of an effective information security policy through ISO27001 (Calder, A., & Watkins, 2010).

BACKGROUND

The ISO/IEC 2700x Family

Several standards, methods and repositories of good practices in information systems security are available. They constitute methodological guides as well as the means to guarantee a coherent security approach.

ISO has undertaken a major effort to streamline existing work, resulting in the ISO/IEC 27000 series of standards. This number corresponds to the reservation of a series of safety standards. To date, only standards 27000, 27001, 27002 and 27006 are published. Some are mandatory to obtain certification, others are mere guides:

- ISO/IEC 27000 presents the vocabulary and definitions of the security field, applicable to each of the standards;
- ISO/IEC 27001 describes the information systems security management policy within a company that serves as a reference for certification;
- ISO/IEC 27002 is the best practice guide for IS security;
- ISO/IEC 27003 is intended to be an implementation guide;
- ISO/IEC 27004 will be a new standard for steering indicators and measurements in the field of IS security;
- ISO/IEC 27005 will be a new standard on risk management for IS security;
- ISO/IEC 27006 summarizes the requirements applicable to external auditors in their ISO 27001 certification assignment.

As shown in Figure 3 below, ISO/IEC 27001 is the center of gravity of the Information security management system ISMS referential.

ISO/IEC 27001

The ISO/IEC 27001 standard, published in November 2005, defines the IS security management policy within a company (Johnson, 2014). It is derived from the BS 7799-2:1999 specification (Specification for Information Security Management Systems) which defines the requirements to be met to create an

Figure 3. The ISO 2700x series

ISMS (PRGL, 2011). It specifies in the annex certain safety controls, taken from the ISO/IEC 17799 standard, the implementation of which is mandatory. ISO 27001 comprises six process areas.

- Define an information security policy.
- Define the scope of the information security management system.
- Conduct a safety risk assessment.
- Manage identified risks.
- Select and implement controls.
- Prepare a SoA (Statement of Applicability).

ISO 27001 specifies the processes that enable a company to build, manage and maintain an information security management system. It integrates the process approach and the PDCA (Plan-Do-Check-Act) cycle of continuous improvement already contained in ISO 9001 and ISO 14001 standards:

- **Plan:** Organize the implementation of the information security management system;
- **Do:** Set up and operate the system ;
- **Check:** Monitor system effectiveness through internal audits and risk assessments;
- **Act:** Improve the system through appropriate corrective and preventive actions, maintain it through communication and training actions.

In terms of security, the improvement loop is synonymous with a risk reduction loop. In practice, procedures should be put in place for:

Figure 4. PDCA cycle

- Quickly detect processing errors;
- Immediately identify any non-compliance with safety rules and organize the immediate reporting of incidents;
- Verify that all safety-related tasks are actually performed, whether by men or automatons;
- Identify the actions to be taken to correct non-compliance with safety rules.

As regards control, regular reviews of the effectiveness of the system should be carried out on the basis of audit results, incident reports and suggestions and comments received from the parties concerned. On the other hand, acceptable residual risk levels must be continuously reviewed and adapted in the light of organizational, technological, legal and regulatory developments or public opinion.

Measurement requirements are explicitly contained in the standard in the form of risk assessments, audits, incident data collection and non-compliance. However, the standard lacks metrics that would make it easier to compare certified entities with a single repository.

ISO/IEC 27002:2005 (revised by ISO/IEC 27002:2013)

ISO/IEC 27002:2005 is another generic standard that can be applied to health information systems to ensure security. It establishes general principles and guidelines for effective initialization, implementation, maintenance and improvement of information security management. The objectives outlined therein provide general guidance on the commonly accepted goals of information security management. Thus any organization seeking to adopt a comprehensive information security management program or improve its existing information security practices can use the standard. The ISO standard asserts that information can be protected using a wide variety of controls. Such controls include hardware and software functions, procedures, policies, processes and organizational structures. Organizations including healthcare organizations, must develop, implement, monitor, evaluate and improve these types of security controls (PRGL, 2011).

ISO/IEC 27002:2005

ISO/IEC 27002 2005 is entitled Information technology - Security techniques - Code of practice for information security management. It is published by the International Organization for Standardization (ISO) and International Electrotechnical Commission (IEC).

ISO/IEC 27002:2005 was developed from BS7799, a British standard that was published in the 1990s. ISO/IEC adopted this standard as ISO/IEC 17799:2000 in December 2000. In June 2005, the standard was revised and officially published as ISO/IEC 17799:2005. On July 1, 2007, it was renumbered ISO/IEC 27002:2005 to align with the other ISO/IEC 27000-series standards (ISO/IEC, 2013). On the other hand, ISO/IEC 27002:2005 has been revised by ISO/IEC 27002:2013 (ISECT, 2012).

In this research, ISO 27001 serves as the framework for measuring information security in organizations. It is surprisingly well suited to this work, as the idea behind ISO 27001 is to have a list of controls that should be able to mitigate all possible information security risks.

ISO/IEC 27002:2005

The thirty-nine main security categories of the standard are specified under eleven security control clauses. Each main security category contains one control objective stating what is to be achieved. In addition, one or more controls are specified to help achieve the control objective. The standard also has one introductory clause that discusses risk assessment and treatment. The control clauses include:

1. Risk assessment and treatment
2. Security policy
3. Organization of information security
4. Asset management
5. Human resources security
6. Physical and environmental security
7. Communications and operations management
8. Access control
9. Information systems acquisition, development and maintenance
10. Information security incident management
11. Business continuity management
12. Compliance

Although ISO/IEC recommends a complete consideration of the practices, organizations do not have to implement every recommended security practice stated therein. The important thing is to know what works best for the unique information security risks and requirements (ISO/IEC, 2013).

ISO / IEC 27001: 2013 now contains 114 controls for 14 domain areas as shown in table 1 below (ISO/IEC, 2013):

Information Security Policies

Objectives: To establish an Information Systems Security Policy published, regularly updated and supported by general management, in order to provide information security guidance in line with business requirements and regulations in force.

Table 1. ISO / IEC 27001: 2013 controls and domains

#	Domain	Number of Controls
1	Information Security Policies	2
2	Organization of Information Security	7
3	Human Resource Security	6
4	Asset Management	10
5	Access Control	14
6	Cryptography	2
7	Physical & Environmental Security	15
8	Operations Security	14
9	Communications Security	7
10	System Acquisition, Development & Maintenance	13
11	Supplier Relationships	5
12	Information Security Incident Management	7
13	Information Security Aspects of Business Continuity	4
14	Compliance	8

The ISSP centralizes the organization's information protection strategy. It is validated by the COSI and approved by the General Management and is available to all the organization's agents and transmitted to the third parties concerned.

Organization of Information Security

Objectives: To manage, monitor and guarantee the security of information within the organization in a transversal way, and to define the responsibilities and roles of the various security actors.

The organization of information security clause addresses the need to define and allocate the necessary roles and responsibilities for information security management processes and activities. This includes controls related to the definition of information security roles and responsibilities, segregation of duties, contact with authorities, contact with special interest groups, information security in project management and mobile devices and teleworking.

Human Resource Security

Objectives: To ensure that employees and contractors understand their responsibilities and are suitable for the roles for which they are considered. •To ensure that employees and contractors are aware of and fulfill their information security responsibilities. And to protect the organization's interests as part of the process of changing or terminating employment.

The Human Resource Security clause addresses the required controls for processes related to staff recruiting, their job during employment and after the termination of their contracts. These considerations should include information security coordination, allocation of information security responsibilities, authorization processes for information processing facilities, confidentiality agreements, contact with authorities, contact with special interest groups, independent review of information security, identifica-

tion of risks related to external parties, addressing security when dealing with customers, addressing security on contractors' agreements, etc.

Asset Management

Objectives: To identify, inventory and classify all assets required for information management. For each of them, a person in charge must be identified. The latter is responsible for enforcing the security policy for its assets.

The asset management clause addresses the responsibilities that need to be defined and assigned for asset management processes and procedures. The owner of the assets and other parties involved in this issue should be identified to be held responsible for the security of the assets, including classification, labeling and information processing; and the information processing facilities should be identified and maintained. In addition, this clause addresses the control of removable media management, media disposal and physical media transfer.

Access Control

Objectives: To ensure that users are aware of security responsibilities. To reduce the risk of accidents, errors and/or malicious acts by integrating safety principles into human resources management, from recruitment to the end of collaboration

The access control clause addresses the requirements for controlling access to information assets and information processing facilities. Controls focus on protection against accidental damage or loss, overheating, threats, etc. This requires documented control policies and procedures, registration, removal and review of user access rights, including here physical access, access to the network and control of privileged utilities, and restriction of access to program source code.

Cryptography

Objectives: To ensure proper and effective use of cryptography to protect the confidentiality, authenticity and/or integrity of information.

The Cryptography clause addresses policies on cryptographic controls for protection of information to ensure proper and effective use of cryptography in order to protect the confidentiality, authenticity, integrity, non-repudiation and authentication of the information. It also includes the need for digital signatures and message authentication codes, and cryptographic key management.

Physical and Environmental Security

Objectives: To ensure the protection and availability of sensitive equipment. To ensure that only authorized persons have access to the organization's buildings, technical and archive premises and that accesses are traced.

The physical and environmental security clause addresses the need to prevent unauthorized physical access, damage and interference to the organization's information and information processing facilities.

Operations Security

Objectives: To ensure correct and secure operations of information processing facilities. To ensure that information and information processing facilities are protected against malware. To protect against loss of data. To record events and generate evidence. To ensure the integrity of operational systems. To prevent exploitation of technical vulnerabilities. To minimize the impact of audit activities on operational systems.

The Operations security clause addresses the organization's ability to ensure correct and secure operations. The controls cover the need for operational procedures and responsibilities, protection from malware, backup, logging and monitoring, control of operational software, technical vulnerability management, information systems audit considerations.

Communication Security

Objectives: To ensure the protection of information in networks and its supporting information processing facilities. To maintain the security of information transferred within an organization and with any external entity.

The communications security clause addresses the organization's ability to protect information in systems and applications of supporting networks and information processing facilities. Controls cover information security in connected networks and services against unauthorized access, transfer policies and procedures, secure transfer of business information between the organization and external parties, information involved in e-mail, the need for confidentiality or non-disclosure agreements.

System Acquisition, Development and Maintenance

Objectives: To guarantee security management throughout the lifecycle of Information Systems. To reduce the risks associated with exploiting technical and application vulnerabilities.

The System Acquisition, Development and Maintenance clause covers controls for identifying, analyzing and specifying information security requirements, securing application services in development and support processes, technical review restrictions on changes to software packages, secure system engineering principles, secure development environment, outsourced development, system security testing, system acceptance testing and test data protection.

Supplier Relationships

Objectives: To ensure protection of the organization's assets that is accessible by suppliers. To maintain an agreed level of information security and service delivery in line with supplier agreements.

The Supplier Relationships clause addresses controls for supplier's relationship issues, including here information security policies and procedures, addressing security within supplier agreements, communication and awareness about technology supply chain and service delivery management.

Information Security Incident Management

Objective: To ensure a consistent and effective policy for the management of information security incidents. To guarantee the reporting of security events and vulnerabilities. To identify indicators and report on security incidents.

The information security incident management clause covers controls over responsibilities and procedures, reporting information and security weaknesses, assessing and deciding on information security events, responding to information security incidents, learning from information security incidents, and gathering evidence.

Information Security Aspects of Business Continuity Management

Objectives: After a minor incident (equipment failure), provide computer backup according to business needs. After a major incident affecting an entire engine room, ensure continuity of IT activity for sensitive assets as quickly as possible and according to business needs.

The business continuity management clause addresses the organization's ability to counter normal business interruptions, including the availability of information processing facilities, verify, review and assess information security continuity, implement information security continuity and plan information security continuity.

Compliance

Objectives: To avoid any violation of intellectual property, legal, regulatory and contractual provisions and security requirements of the organization.

The compliance clause addresses the organization's ability to comply with regulatory, statutory, contractual and security requirements, including identification of applicable laws and contractual requirements, intellectual property rights, record protection, confidentiality and protection of personally identifiable information, regulation of cryptographic controls, independent review of information security, compliance with security policies and standards, and review of technical compliance.

Other ISO 27000 standards

In addition to ISO 27001 and 27002, there are several other ISO standards in the 27000 range. These other standards guide and support ISO 27001/27002 for both organizations and auditors.

ISO 27003

ISO 27003 is used as the implementation standard for ISO 27001. This standard is intended to obtain management approval, define CMSS, conduct an organizational analysis and a risk analysis.

ISO 27004

ISO 27004 is a standard that helps measure the effectiveness of ISMS. ISO 27004 includes the following chapters:

- Overview of Information Security Measurement; Management Responsibilities;
- Measurement and measurement development;
- Measurement operation;
- Data analysis and reporting on measurement results;
- Evaluation and improvement of the information security measurement program.

ISO 27005

ISO 27005 is a standard that provides guidance for the implementation of ISO 27001. ISO 27005's approach begins by setting the context - defining the scope (primary processes and related assets) and boundaries of the organization. When defining the scope, a risk analysis will be carried out. Risk analysis consists of identifying the assets and the threats they face. In addition, the impact of a successful exploitation of a certain threat must be analyzed. When this is done, for each threat, an estimate of the likelihood that the threat will be successfully exploited will be multiplied by the costs of the impact of that exploitation. Based on this list, each risk should be mitigated through the implementation of controls, risk acceptance, risk avoidance or risk transfer.

RESEARCH METHODOLOGY

Data Collect

As part of this research, MENA large organizations experts are interviewed. These experts hold the title of a security officer, or what most closely resembles their organization. We chose the large public sector organizations because there are interesting problems specific to this sector. For example, government organizations usually possess many privacy-sensitive data - e.g., information about citizens. In addition, it appears that data leaks from public bodies are often well exposed in the media.

For the first round. We mailed a letter with details of the research content, what they would be asked for and what their own benefits were, before sending the final question, which is an optimized version of the ISO 27001 questionnaire presented. A total of 20 organizations were selected, 6 organizations agreed to give us interviews to answer our questions, i.e. 30%, a percentage too credible for this research.

In the second round, we validate the first study result with a qualitative methodology through a case study in a large public organization in Morocco.

As we conducted interviews by e-mail, we did not need to go to the locations of the interviewees. Therefore, the interviews did not require travel expenses. When participants sent me answers that we could not understand, we could then ask them to give me more details or explanations on previous comments. The email interviews allowed us to interview several participants at the same time. They were also easy to transcribe. At the same time, there was a lack of richness in the responses we received from participants. It was also not easy for participants to get clarification on the meaning of the questions, so we sent them a brief explanation of the theories by email. These explanations would improve their possibilities if they gave appropriate answers. Table 2 shows a summary of key attributes of participating organizations.

Data Analysis

For each interview, a report was written. The size was limited to about one page. The following section contains the reports from each interview. For reasons of anonymity, organizations are indicated by alphabets from A to F. The questionnaire results for each organization are presented in the next section. For each organization, the scores for each sub-theme are displayed.

The data were collected by means of a Likert scale from 0 to 5 (5: Very Important; 4: Important, 3: Moderately, 2: Slightly Important, 1: Unimportant). The items for each construct are adopted from

Table 2. Summary of key attributes of MENA organizations

Organizations	A	B	C	D	E	F
No of employees	1125	2400	7000	12000	2400	1700
No of IT staff	80	190	220	420	44	35
No of IT Security staff	5	12	9	10	3	5
Government (Gov.)/ Multinational (multi.)	Gov.	Gov.	Gov.	Gov.	Gov.	Gov.
ISO 27001 Version	2013	2013	2013	2013	2013	2013
Certified ISO 27002 Lead auditor staff	6%	5%	3%	3%	7%	0%

previous studies and each question relates to an item (Bergner, Witherspoon, Cockrell, & Stone, 2013; Pat & Piattini, 2011). To estimate the extent of non-respondent bias, it was not possible to compare respondents with non-respondents' answers. This is because the survey was anonymous and we had access only to names and e-mail addresses of participants, unlinked to their responses, and not those who chose not to participate. As a result, a non-response bias test was undertaken by comparing early respondents with late respondents instead (Lewis-Beck, M., Bryman, A. E., & Liao, 2003).

Discussion and Finding

The following figure 5 provides an overview of how the six organizations ranked for each of the sub-themes.

For organization A, E and F there is no specific security agent. However, one group of people is responsible for information security. The Information Security Policy was created in 2012 and is approved by management. However, the IT security policy is not signed by management.

For these organizations, the most important controls are those related to information security, for example, high-level policies, risk assessment. This means that the following three documents must exist and be signed by management:

Table 3. ISO 27001 Metrics

Status	Meaning	Proportion of ISMS requirements	Proportion of information security controls
Unimportant	Development has barely started and will require significant work to fulfill the requirements	%	%
Slightly important	Progressing nicely but not yet complete	%	%
Moderately important	Development is more or less complete although detail is lacking and/or it is not yet implemented, enforced and actively supported by top management	%	%
Important	Development is complete, the process/control has been implemented and recently started operating	%	%
Very Important	The requirement is fully satisfied, is operating fully as expected, is being actively monitored and improved, and there is substantial evidence to prove all that to the auditors	%	%

Figure 5. Organizations maturity rating through ISO/IEC 27001:2013

- Information Security Policy Information Technology Policy
- Classification of information sources

Security awareness should also be emphasized. In these organizations, awareness training is organized so that employees are knowingly incompetent in information security, rather than unconsciously incompetent.

Management should become more aware of safety issues themselves in order to play an exemplary role vis-à-vis, other employees. An example of this is: According to the information security policy, identification badges must be displayed at all times. Management does not do it itself.

Organization E. One of the major problems within the organization is that information security is not an integral part of the organization, but something that is considered an IT problem. This results in several problems for the security guard, for example:

- Lack of management commitment - information security policy has not been approved/signed by management.
- Not all information security issues are technical. For example, in the past, employees did not need a non-disclosure agreement. This situation changed in the spring of 2014, requiring all new employees to sign a non-disclosure agreement.
- There is no confidentiality classification for the information.
- There is no list of processes within the organization.
- There are several courses for employees, for example, a LinkedIn course or an Office course.

However, information security is little or not taken into account in these courses. Employees know little about how their actions (online) could harm the organization's image.

All contracts with third parties contain information security clauses. This includes cleaners. An outside company disposes of used paper and hard drives.

There are employment procedures, both for new employees and for dismissals. However, these procedures are not always followed correctly - employees only get more access rights and almost never less, even if their work no longer requires it. It is possible for employees to work from home. Authentication works with an SMS token, which gives the user access similar to what is possible in the office.

For organization F. For the moment, there is still no information security policy. However, interviews were conducted with experts within the organization to develop a list of ISO 27001 controls that should be implemented.

The systems used are shared with other organizations in a shared service centre. This centre also includes a service desk for incidents. For high priority incidents, a process is in place that includes management and impact analysis. Physical access is regulated by the use of tokens, where access is distributed according to need. Utility offices have emergency buttons that can be used in the event of disturbance in freely accessible areas. At night, the inner courtyard is locked with fences by the security team.

The organization has undergone intrusion tests, for example using a mystery guest. A mystery guest is a person hired by the organization to pose as a stranger trying to access critical information. This mystery guest made a video about how to get in. This video was shown to management to raise awareness.

It is possible to bring a mobile phone or a tablet computer. There are three different wireless networks - a public network, one for guests and one for employees. These use a ticket system, which allows only one device for a certain time. Thereafter, a new ticket must be requested.

Basically, information security is always a secondary issue, and the level of maturity switches between level 1 (ad hoc) and 2 (repeatable). Efforts must be made to complete level 3 (defined) and 4 (managed), especially in the areas of asset management, operation management, supplier relationships, business continuity and compliance.

For organizations B, C and D. Within these organizations, ISO 27001 is used as a guideline for information security. Currently, a baseline is applied across these organizations.

On third parties: Paper waste is disposed of by a company specializing in organization C and D. For as much software as possible, a SaaS solution is used. However, change management is always done within the organization. Backups are performed regularly and tested. Physical security has three different zones: Public areas, employee areas and specific areas, such as server rooms. Organizations support telework through a VPN virtual private network.

For organizations C and D. In these two organizations, a difference is made between the information security policy and the information security plan. The policy is higher than the plan. The plan is based on ISO 27001 controls. Controls are selected using a risk analysis: A matrix of estimated risks and impacts is established and serves as the basis for the selection of controls.

Employees of these organizations were not sworn in, with the exception of temporary staff. Instead, they must sign a non-disclosure agreement. Employees are informed of information security through intranet bulletins, but there is no policy in place for security awareness training.

For third parties, for example application hosting, information security clauses are either included in the terms of service or included in the contract.

A third party takes care of all the equipment that needs to be disposed of, including paper, old computers, printers, etc. When it comes to new applications, ready-to-use solutions are preferred to custom software. If necessary, they can be modified to meet additional needs. For large requests, a tendering

procedure is organised. There is a formal change management process, which has improved considerably in recent years.

There are several networks within this organization, and they are physically or virtually separate. For example, there is a network on which employees are connected, one for servers, a public wireless network, a wireless network for employees. Both can be used for mobile devices and are therefore not connected to other networks.

Each week, a list of terminated employees is generated and used to ensure that these employees no longer have access to the applications. There is an employee transfer procedure. However, since a transfer may take some time during which the employee may still need their former access rights, it is more difficult than hiring and termination.

It is possible to work from home. A virtual office system is used, giving a virtual workplace at home. In the future, the computers in the office will use the same system. In the office, all office spaces are flexible: no fixed rooms for employees.

For incidents, a form exists on the intranet for organization E. Depending on the incident, it is assigned either to facilities management or to IT. There, priority is given, depending on the impact of the incident. There is an escalation procedure: the more important an incident is, the more important the follow-up of an incident is. This may be management or a subsequent evaluation.

In general, the 3 organizations are at level 3 (defined). At least efforts must be made in areas such as cryptography and Information security aspects of business continuity management.

CONCLUSION

The objective of this study was to establish a practical framework for the formulation and implementation of the IS security policy. The problem arising from this situation is an ineffective IS security policy and, therefore, a vulnerable system. To achieve this objective, we reviewed the ISO 20001 security policy frameworks and conducted a case study in six organizations to define the IS policy maturity state.

The maturity level assessment reflects the organization's ability to implement and maintain its security system, in order to ensure the identification and regular assessment of risks, the implementation, management and audit of controls to deal with these risks.

Improving the level of information security management requires significant technical, human and organizational resources that must be deployed and managed at all levels of organizations.

To conclude, it can be said that the process of implementing an effective IS security policy depends above all on the involvement of employees and the top management. The level of security required also depends on the need of the organization.

In general, an effective information security management system must establish a continuous improvement cycle to keep the level of security maturity at an acceptable level.

FUTURE RESEARCH DIRECTIONS

Further research is needed to determine the situation within more controlled environments, such as commercial or private organizations. Being a state educational entity may have distorted the results to a degree and having additional, more diverse data would validate the framework to a greater level. Also,

this study focused on the relatively small subset of those most directly involved in policy. A quantitative examination of a wide base of users might shed some additional light on policy implementation.

KEY TERMS AND DEFINITIONS

Authentication: Is the process of verifying a claim of identity. Three different types of information can be used for authentication: something you know (a PIN, a password, mother's maiden name), something you have (magnetic swipe card) or something you are (biometrics).

Availability: Information and supporting IT systems should be available to authorised users when needed.

Confidentiality: Data or information prevented from the exposure to unauthorized individuals is labeled as confidential.

Encryption: The action of changing the information by using an algorithm to make it unreadable to anyone.

Information Security: Is defined as “a well-informed sense of assurance that information risks and controls are in balance”. The goal of information security is to protect business assets and reduce costs by avoiding security violations and reducing the negative effects they have on an organization.

Information Security Policy: Is a written, living document outlining the actions and procedures that employees should follow in order to protect an organization's information security assets, an information security policy outlines the function and tasks of employees in order to protect an organization's information assets.

Integrity: Integrity is the quality of being whole, uncorrupted and complete.

ISMS: An information security management system (ISMS) is a tool that helps organizations to establish, implement, operate, monitor, review, maintain and improve the desired level of information security in the organization.

ISO/IEC 27001:2013: Information security standard published by the International Organization for Standardization (ISO) and by the International Electrotechnical Commission (IEC), entitled Information Technology – Security Techniques – Information Security Management Systems – Requirements.

ISO/IEC 27002:2013: Information security standard (list of controls) published by the International Organization for Standardization (ISO) and by the International Electrotechnical Commission (IEC), entitled Information Technology – Security Techniques – Code of practice for Information Security - Controls.

Top Management: High level management.

Vulnerability: Is a weakness in the organization, network that can be exploited by a threat.

Auditor Evaluation and Reporting on Cybersecurity Risks

University of West Florida, USA

INTRODUCTION

Just a few decades ago information systems consisted primarily of mainframe computers with what were commonly referred to as “dumb terminals” that granted access into a mainframe computer which performed an organization’s information processing. The risk of intruders accessing such systems was significantly less and physical security measures such as locked doors and security guards served as an effective approach in protecting information systems from outsiders. Substantial information processing capabilities were then added with the widespread use of the Internet, company networks, and the distribution of computing power to the end user. Unfortunately, it also resulted in an immense increase in the danger of outsiders hacking into company information systems gaining access to sensitive information and causing various types of malicious behavior.

A recent cybersecurity attack at the Marriott hotel chain illustrates what can happen when cybersecurity incidents occur and are not thoroughly resolved. In 2015, Marriott Hotels acquired another hotel, known as Starwood Hotels and Resorts Worldwide, as part of a \$13.6 billion deal which made Marriott the No. 1 hotel chain in the world. Four days after the announcement of this 2015 merger, Starwood stated that credit card information had been stolen in some of its hotel restaurants and gift shops as a result of malware that attackers installed on point-of-sale systems in 2014. In December 2018, The Wall Street Journal reported the theft of personal information for up to 500 million customers as a result of a hack of Marriott’s customer database for its Starwood properties. Although Marriott claimed that the 2018 discovery was unrelated to the prior incident, security experts believe that a more thorough investigation of the initial intrusion would have identified a second intruder who was able to stay in the Marriott reservation system for the more than three years following the initial security breach (McMillan, 2018).

The objectives of this research are to provide an overview of some of the considerations that are involved in an assessment of an organization’s system of cybersecurity including: lines of defense, audits and reporting, and standards and frameworks for evaluation. This article begins by considering challenges facing today’s audit committees, the need to understand the common profile of the cyber perpetrator, and the necessity of employee training to overcome complacency in dealing with cybersecurity risks. This is followed by guidance from both the Institute of Internal Auditors (IIA) and the American Institute of Certified Public Accountants (AICPA). A thought-provoking discussion based on IIA literature considers what the IIA refers to as “three lines of defense” to address risks in today’s cyber environment. Guidance from the AICPA describes reporting on an entity’s cybersecurity risk management program and controls. In the audit of security systems to address cybersecurity risks, it is also essential to make use

DOI: 10.4018/978-1-7998-3473-1.ch082

of standards and frameworks to facilitate a proper evaluation. This is also addressed by considering how guidance from COBIT, the National Institute of Standards and Technology, and the Center for Internet Security can be mapped into five cyber infrastructure domains.

BACKGROUND

A primary focus of an audit committee is to provide an independent oversight function to ensure that the processing and storage of information is performed in a secure and reliable manner to meet the needs of information users. Although the birth of the Internet and extensive networking capabilities has substantially increased the ability of organizations to process and disseminate information, it has also opened the door to allow greater access to information systems by unauthorized and many times malicious intruders. It is certainly a difficult task to address these security issues due to the constantly changing availability of technology that is both within and outside of an organization's control. This section discusses challenges faced by audit committees as a result of cybersecurity issues. It also considers common profiles of the cyber perpetrator and how noncompliance with information security policy by well-meaning organizational personnel can allow unauthorized access into an organization's information system.

Challenges Facing Today's Audit Committee

Lanz (2014) points out that today's audit committee faces challenges in their governance of cybersecurity, including:

- Organizations must reconcile between the availability of products and services to enable business in cyberspace and protecting information in accordance with business and regulatory requirements.
- The periodic briefings that information security professionals provide to audit committee members may not be relevant enough for them to properly perform governance duties.
- Lack of cybersecurity training for organization personnel can serve as a weak link despite large investments in information security technology.
- Organization's that rely on third parties to provide information processing services should ensure that a vendor management program exists to provide evidence that the vendor follows due diligence to protect sensitive information.

Common Profiles of the Cyber Perpetrator

Galligan and Rau (2015) stress the importance of having a risk assessment process that considers the cyber risk profile(s) most likely to pose a threat to an organization. They point out that certain industries may be more susceptible to a specific type of cyberattack. They describe the following broad categories of perpetrators:

- **Nation-states and Spies:** Involve hostile foreign nations looking to obtain trade secrets and intellectual property to achieve competitive and military advantages.
- **Organized Criminals:** Involve persons seeking to steal money and private information such as through identify theft of an organization's customers.

- **Terrorists:** Involve persons who want to launch cyberattacks against important infrastructure such as banks.
- **Hacktivists:** Involve persons who desire to make a political or social statement through the theft or publication of sensitive organization information.
- **Insiders:** Involve persons who are trusted members of an organization that want to sell or share sensitive information.

Organizational Noncompliance

Although the ability of an organization to deal with the malicious behavior of persons is certainly an issue that must be considered, another significant threat arises from insiders who intend no harm to the information system but simply fail to understand and follow appropriate security policies. Stafford, Deitz, and Li (2018) posed the research question: “How can auditors identify and contribute to the correction of non-malicious insider threats to cybersecurity in the firm?” Through two specific case studies and depth interviews with trained auditors, these researchers defined and considered the following types of non-malicious insider threats:

- **CyberComplacency:** Computer users who are less concerned about cybersecurity diligence than their company would like because they believe they are working with invulnerable platforms.
- **Cybersecurity Loafing:** technically competent employees who take unauthorized steps to bypass specific security policies in order to achieve greater workgroup efficiency.

The results of the research concluded that applying sanctions against employees for these non-malicious threats is less effective than having information system auditors consult with system users to better educate them regarding system vulnerabilities and the importance of following established information security policy.

FOCUS OF THE ARTICLE

Auditing standard setters from the Institute of Internal Auditors and the American Institute of Certified Public Accountants have issued guidance about lines of defense and reporting on an entity’s cybersecurity risk management program and controls, respectively. Standards and frameworks from COBIT, the National Institute of Standards and Technology, and the Center for Internet Security can be used in the evaluation of a system of cybersecurity.

Internal Audit and Cybersecurity

The Institute of Internal Auditors (IIA) (2016) defines cybersecurity as “the technologies, processes, and practices designed to protect an organization’s information assets – computers, networks, programs, and data – from unauthorized access.” They also point out that the risks of cybersecurity extend well beyond the general and application controls that internal audit has traditionally assessed in regard to information technology. This increased risk is largely attributable to global connectivity that allows persons outside of the organization to access information. To address this additional risk, the IIA suggests that organizations have in place three lines of defense.

The First Line of Defense

The IIA (2013) states that “operational management naturally serves as the first line of defense because controls are designed into systems and processes under the guidance of operating management.” The key aspect of the first line of defense is to ensure that appropriate positions of responsibility are established and staffed with qualified talent to address current and emerging cybersecurity issues. The IIA (2016) includes the following examples of key operating management positions that can be established:

- **Chief Technology Officer (CTO):** Responsible for supplying knowledge and direction regarding the availability of technologies to guide the organization’s mission. The CTO is often responsible for protecting the intellectual property of the organization.
- **Chief Information Security Officer (CISO):** Serves as a foundation in the identification and understanding of cyber threats. The CISO often takes a lead role in the development of oversight programs to ensure the protection of organization assets and stakeholder data.
- **Chief Information Officer (CIO):** Acts to drive an organization’s competitive advantage and strategic change. The CIO is often responsible for developing an information cybersecurity program and implementing entity-wide cybersecurity training.

In situations where it may be impractical to establish the above positions, the assignment of the various cybersecurity responsibilities can be approached through “a council of business and information technology (IT) managers who have a stake in responding to cybersecurity risk.” The IIA (2016) also identifies some specific examples of activities in the first line of defense including:

- Administration of security procedures, testing, and training.
- Putting in place intrusion detection systems and handling penetration testing.
- Maintenance of an inventory of technology devices, information assets, and associated software.
- Recruiting and retaining appropriately certified IT talent.

The Second Line of Defense

The IIA (2013) explains the second line of defense as being what management does to set up “various risk management and compliance functions to help build and/or monitor the first line of defense controls.” The IIA (2016) mentions the following three points in describing the responsibilities of the second line of defense:

- An assessment of cybersecurity risks and exposures to evaluate whether they are in line with the risk appetite of the organization.
- Monitoring the organization for changes in legal requirements and risks.
- Working with the functions established in the first line of defense to make certain that suitable controls are designed.

The second line of defense therefore involves the specific activities that operating management implements to ensure cybersecurity risk control and compliance (IIA 2013).

The Third Line of Defense

The IIA (2013) defines the third line of defense as having an organization's "internal auditors provide the governing body and senior management with comprehensive assurance based on the highest level of independence and objectivity within the organization. This high level of independence is not available within the second line of defense." The IIA (2016) uses the following points to illustrate some of the activities of the third line of defense:

- Provide regular independent evaluations of preventive and detective measures regarding cybersecurity issues.
- Track the diligence with which remediation takes place to address identified cybersecurity concerns.
- Work with the second lines of defense to perform cybersecurity risk assessments of various third parties including service organizations and suppliers.

The Cybersecurity Risk Management Examination

In May 2017, the American Institute of Certified Public Accountants (AICPA) issued an attestation guide entitled "Reporting on an Entity's Cybersecurity Risk Management Program and Controls" ("Cybersecurity Guide"). In contrast to a CPA's evaluation of internal accounting controls that is integrated with an audit of a public company's financial statements, which focuses exclusively on objectives of external financial reporting, a more detailed examination is required for a CPA to attest to whether an entity's cybersecurity risk management program achieves an organization's overall business objectives.

The Standard Examination Report

The cybersecurity risk management report can cover a specific point in time or be for a period of time. Three major components of the report include:

1. Management's description of the entity's cybersecurity risk management program consists of a narrative that describes how an organization identifies its information assets, defines management's approach to dealing with the cybersecurity risks faced by those assets, and describes the primary security policies and processes that have been put into operation to protect its information assets.
2. Management's assertion addressing whether (i) "the description is presented in accordance with the description criteria and," (ii) "the controls within the entity's cybersecurity risk management program were effective to achieve the entity's cybersecurity objectives based on the control criteria." (See section on "Assessing Cybersecurity Objectives").
3. Practitioner's report stating separate opinions on whether the components of management's assertion described above have been met. (See section on "Forming the Opinion").

It should be recognized that due to the high likelihood of security events or breaches, a cybersecurity risk management program is considered effective if the program can detect security events in a timely manner and recover from them with a minimum amount of disruption to company operations.

Assessing Cybersecurity Objectives

One of the first issues in dealing with an evaluation of an organization's Cybersecurity Risk Management Program involves an evaluation of whether management's description of the program includes appropriate cybersecurity objectives that address specific cybersecurity risks that the organization faces. The Committee of Sponsoring Organizations of the Treadway Commission (COSO) framework points out criteria that can be used to evaluate whether cybersecurity objectives are appropriate, including that they:

- **Specifically explain** cybersecurity risks that need to be lessened;
- **Are measurable or observable** so that it can be determined whether the objective has been met;
- **Are attainable** in that controls can be implemented that if suitably designed and complied with can achieve each objective;
- **Are relevant** in that they support the organization's overall objectives including the availability of system processing, confidentiality of information, and the integrity of both system data and processing;
- **Are time bound** to represent the desired functioning of cybersecurity controls over time.

If a practitioner were to conclude that management's cybersecurity objectives were either incomplete or not suitable, the issues should be brought to management's attention so that they can be addressed. A lack of willingness on the part of management to make appropriate revisions could result in either the practitioner's refusal to accept the engagement or restricting the use of the report to those who understand the risks not addressed.

Forming the Opinion

The opinion that the practitioner expresses in a cybersecurity risk management examination covers two different but related subject matters:

1. Description of the entity's cybersecurity risk management program, and
2. The effectiveness of controls within the program to achieve the entity's cybersecurity objectives.

Table 1. Other opinion possibilities

Nature of Matter Giving Rise to the Modification	Practitioner's Professional Judgment About the Pervasiveness of the Effect or Possible Effects on the Description or on the Effectiveness of Controls	
	Material but Not Pervasive	Material and Pervasive
Scope limitation · The practitioner is unable to obtain sufficient appropriate evidence.	Qualified opinion	Disclaimer of opinion
Material misstatements · Subject Matter 1: The description is materially misstated. Or · Subject Matter 2: The controls were not effective to achieve the entity's cybersecurity objectives.	Qualified opinion	Adverse opinion
It is possible for different opinions to be issued regarding the two subject matters.		

An unmodified report is a report in which the auditor feels that the above subject matters have been appropriately addressed. Table 1 taken from the Cybersecurity Guide presents some other opinion possibilities.

The Design-Only Examination

In situations where an organization has either a very young or significantly changed cybersecurity risk management program, it may be appropriate to temporarily bypass forming an assertion about the effectiveness of controls to accomplish cybersecurity objectives until the program has had more time to actually function. In such situations, the Cybersecurity Guide points out that the design-only report would just address:

1. “The description of the entity’s cybersecurity risk management program and
2. The suitability of the design of the controls implemented within that program to achieve the entity’s cybersecurity objectives.”

Practitioners should consider restricting the use of a design-only report to the client’s board members, organizational personnel, and specific third parties likely to understand it.

Examining a Portion of the Cybersecurity Program

Although the Cybersecurity Guide addresses an entity-wide evaluation, it also points out that management may elect to have only a portion of the program evaluated. The determination of the acceptability of this limited evaluation depends on whether the subject matters of the engagement are expected to appropriately address the needs of the intended users. For example, such a situation could exist if an organization intends to sell off a portion of their operations and intends to examine only the independent program issues of that segment to address the needs of the prospective buyers. In any case involving a partial examination, a practitioner should evaluate whether it is appropriate to restrict report usage to a limited group of users.

Standards and Frameworks for Auditing Cybersecurity

Standards provide a set of rules that can be monitored for compliance by a specialized field’s authoritative bodies and related professionals. The grouping of rules and related concepts into appropriate frameworks furnishes the basic building blocks to identify and decide upon appropriate courses of action to address complex problems. Although the enumeration of an exhaustive set of standards and frameworks appropriate for a cybersecurity audit is beyond the scope of this article, this section presents standards and frameworks selected from four prominent and published works including contributions from the ISACA (formerly known as Information Systems Audit and Control Association), the National Institute of Standards and Technology (NIST), and the Center for Internet Security (CIS). These published works cover, in an overlapping manner, the Risk Management Framework (RMF) as set out by the NIST.

COBIT® 2019

COBIT® 2019 is a framework for the governance and management of enterprise information and technology whose purpose is to facilitate the achievement of the enterprises' goals (ISACA, 2019). It provides control objectives with which the effectiveness of Information Technology (IT) controls can be evaluated. While the governance objectives of COBIT ® 2019, are grouped into the three domains: Evaluate, Direct and Monitor; the management objectives are group into the following four domains (ISACA, 2019):

1. **Align, Plan, and Organize (APO):** Addresses the overall organization, strategy and supporting activities for Information and Technology (I&T).
2. **Build, Acquire and Implement (BAI):** Deals with the definition, acquisition, and implementation of I&T solutions for the enterprise.
3. **Deliver, Service and Support (DSS):** Is concerned with the delivery of secure operations and support of I&T services.
4. **Monitor, Evaluate and Assess (MEA):** Addresses the performance monitoring and conformance of I&T with performance targets, internal control objectives and external requirements.

NIST SP 800-37

The *National Institute of Standards and Technology (NIST) Special Publication (SP) 800-37, Revision 2* (also known as *Risk Management Framework for Information Systems and Organizations A System Life Cycle Approach for Security and Privacy*) (NIST, 2018) describes the Risk Management Framework (RMF) and provides guidelines for applying the framework to information systems within an organization with the intent of helping the organization manage its security and privacy risks. The RMF promotes real-time risk management and common control authorization through a continuous security monitoring process. The seven steps of RMF are as follows:

1. **Prepare:** Requires the establishment of context and priorities in preparation for the management of security and privacy risks.
2. **Categorize:** The systems and information are properly triaged based on the analysis of the impact of loss.
3. **Select:** In order to properly mitigate the identified risks, initial sets of controls are selected.
4. **Implement:** The controls are implemented and described.
5. **Assess:** The implemented controls are assessed and evaluated.
6. **Authorize:-** The system and the common acceptable controls are authorized.
7. **Monitor:** The system and controls are continuously monitored, documented, evaluated, and improved.

NIST SP 800-53

National Institute of Standards and Technology (NIST) Special Publication (SP) 800-53 Revision 4 (also known as *Security and Privacy Controls for Federal Information Systems and Organizations*) (NIST, 2015) describes a set of standards and guidelines to help federal agencies and partners meet the requirements set by the Federal Information Security Management Act (FISMA), which was signed into law as part of the Electronic Government Act of 2002. The law applies to any component of an information

system that stores, processes, or transmits information. The security controls specified in this set are divided into 18 families of controls that are categorized according to severity as being: Low-impact, Moderate-impact and High-impact.

Center for Internet Security Controls

Center for Internet Security (CIS) Controls (CIS, 2019) are best practice guidelines for computer security that were initially developed and introduced by the SANS Institute in 2008 and later transferred to the Center for Internet Security (CIS) in 2015. The 20 CIS Controls, also known as CIS Critical Security Controls, are delineated into three groups: Basic, Foundational and Organizational. These controls are developed by leading security experts and, if correctly implemented, could reduce security risks and operational costs and thereby, significantly improve an organization's defensive posture. The 20 CIS Controls (CIS, 2019), grouped into Basic (**B**), Foundational (**F**), and Organizational (**O**), are as follows:

1. (**B**) Inventory and Control of Hardware Assets
2. (**B**) Inventory and Control of Software Assets
3. (**B**) Continuous Vulnerability Management
4. (**B**) Controlled Use of Administrative Privileges
5. (**B**) Secure Configuration for Hardware and Software on Mobile Devices, Laptops, Workstations and Servers
6. (**B**) Maintenance, Monitoring and Analysis of Audit Logs
7. (**F**) Email and Web Browser Protections
8. (**F**) Malware Defenses
9. (**F**) Limitation and Control of Network Ports, Protocols and Services
10. (**F**) Data Recovery Capabilities
11. (**F**) Secure Configuration for Network Devices (Firewalls, Routers and Switches)
12. (**F**) Boundary Defense
13. (**F**) Data Protection
14. (**F**) Controlled Access Based on the Need to Know
15. (**F**) Wireless Access Control
16. (**F**) Account Monitoring and Control
17. (**O**) Implement a Security Awareness and Training Program
18. (**O**) Application Software Security
19. (**O**) Incident Response and Management
20. (**O**) Penetration Tests and Red Team Exercises

SOLUTIONS AND RECOMMENDATIONS

The previously presented cybersecurity guidance from COBIT, the National Institute of Standards and Technology, and the Center for Internet Security can be mapped into five cyber infrastructure domains to provide an approach to evaluate a system of cybersecurity.

Cyber Infrastructure Requirements and Controls

The cyber infrastructure is the backbone of the information technology (IT) enterprise. In this research, the authors' based their study on five cyber infrastructure domains--a departure from the more granular seven domains found in a typical IT infrastructure. Figure 1 presents the five cyber infrastructure domains showing that all domains fall within the realm of the Physical Domain.

Figure 1. The five cyber infrastructure domains

For each domain, the authors' examined it, specified its predominant requirements, identified the controls to satisfy the requirements, and mapped those controls to the standards and frameworks that are described in the previous section of this article. The remainder of this section illustrates the application of the standards and frameworks to the requirements and controls that are found in each of the cyber infrastructure domains.

Physical Domain

The *Physical Domain* includes the equipment, devices, mechanisms, policies, and controls that are used to physically secure the cyber assets. Examples of these are locks, gates, fences, alarm systems, computing devices and storage, and badges, among others. The four critical security requirements of the physical domain are as follows:

1. **Security of Physical Access to Assets:** Requires the protection of physical assets through the implementation and monitoring of secure access mechanisms.
2. **Training of Physical Security Personnel:** Involves the periodic training of personnel on both physical and cybersecurity.
3. **Facility Management:** Entails the implementation and enforcement of safety and health policies, the maintenance of facilities to enable smooth operations, the creation of contingency plans including power and data backups, and the record keeping of physical incidents and assets.
4. **Asset Management:** Includes the safeguarding and handling of information assets. It also involves the proper transfer, backup, and destruction of information storage systems and devices.

The mapping of the requirements and controls with the frameworks and standards for the physical domain is depicted in Table 2.

Table 2. The Physical Domain Requirements and Controls

Requirements	Controls	Frameworks and Standards
Secure physical access to assets	· Physical asset and activity monitoring · Event Logs · Physical access mechanism	COBIT 2019: DSS 01.03 CIS: 1, 12, 14 NIST 800-37 Rev 2: Task P-10 NIST 800-53 Rev 4: AC-3, PE-6, PS-1
Physical security personnel adequately trained	· Periodic cybersecurity awareness training	COBIT 2019: APO 07.03 CIS: 17 NIST 800-37 Rev 2: Task P-17 NIST 800-53 Rev 4: AT-2, AT-3, AT-4
Facility management	· Regular monitoring and testing of uninterruptible power supplies · Records of facility incidents · Maintained compliance with safety and health regulations	COBIT 2019: DSS 01.05 CIS: 9, 17 NIST 800-37 Rev 2: Task P-15 NIST 800-53 Rev 4: AC-3, PE-2, PE-3, PE-6
Asset management	· Formal process of disposition, transfer, and removal of IT assets	COBIT 2019: BAI 09.03 CIS: 1 NIST 800-37 Rev 2: Task M-7 NIST 800-53 Rev 4: MP-2, MP-3, MP-4, MP-5, MP-6, PE-20

User Domain

The *User Domain* includes the various users that maintain and interact with the cyber assets. It also includes the access and authorization mechanisms whose purpose is to protect the cyber system from unauthorized access. The four critical security requirements of the user domain are as follows:

1. **Identification and Management of Users:** Entails the documentation and delineation of user responsibilities.
2. **User Training:** It is imperative that all users undergo periodic security awareness security training.
3. **Identity Management, Authentication and Access Control:** The management of user credentials and the provision for user access, authentication and authorization mechanisms.

4. **Continuous Security Monitoring:** Entails the continuous and persistent monitoring of user activities.

The mapping of the requirements and controls with the frameworks and standards for the user domain is depicted in Table 3.

Table 3. The user domain requirements and controls

Requirements	Controls	Frameworks and Standards
Identify and manage users	· Documented cybersecurity roles and responsibilities	COBIT 2019: APO 01.02, 07.06, DSS 06.03 CIS: 17, 19 NIST 800-37 Rev 2: Task S-4 NIST 800-53 Rev 4: AC-1, AC-2, AC-5, AC-6
Train users on cybersecurity awareness	· Periodic cybersecurity personnel awareness training	COBIT 2019: APO 07.03, BAI 05.07 CIS: 17 NIST 800-37 Rev 2: Task P-17 NIST 800-53 Rev 4: AT-2, AT-3, AT-4
Identity management, authentication and access control	· Managed identities and credentials for users · Managed access and authorizations for users · Authentication of users	COBIT 2019: DSS 05.04, 05.10, 06.03 CIS: 1, 5, 12, 14, 15, 16 NIST 800-37 Rev 2: Task M-1 NIST 800-53 Rev 4: AC-1, AC-3, CM-5, CM-10, IA-5
Continuous monitoring of user activities	· Monitored personnel cyber activity for potential cyber incidents	COBIT 2019: DSS 05.07 CIS: 5, 7, 14, 16, 17 NIST 800-37 Rev 2: Task M-2 NIST 800-53 Rev 4: AC-6, AC-7, AC-8

Communication Domain

The *Communication Domain* includes the network systems and peripherals that facilitate the transfer of information from one cyber endpoint to another. It also includes the various communication media, such as fiber optics, copper cables, and radio waves. In addition, this domain considers mechanisms that facilitate secure data transmissions. The five critical security requirements of the communication domain are as follows:

1. **Management of Communication Assets:** Communication assets must be managed and secured. Controls for this requirement include the mapping and tracking of communication flow and a periodic vulnerability assessment of communication assets.
2. **Manage Device Authentication and Access Control:** Entails the provision for device authentication and access control for the protection of system and data integrity and confidentiality.
3. **Network Defense:** Includes securing the network and all its peripherals.
4. **Continuous Monitoring of Network Behavior:** Similar to the constant monitoring of user behavior, network traffic must also be monitored for abnormal behavior.

5. **Incident Response and Recovery:** Entails the creation and maintenance of the organization's incident response and recovery plans.

The mapping of the requirements and controls with the frameworks and standards for the communication domain is depicted in Table 4.

Table 4. The communication domain requirements and controls

Requirements	Controls	Frameworks and Standards
Manage communication assets	· Mapped organizational communication and data flows · Vulnerability assessment	COBIT 2019: DSS 05.02 CIS: 12, 16 NIST 800-37 Rev 2: Task A-3 COBIT 2019: APO 12.01, 12.02, 12.03 CIS: 3 NIST 800-53 Rev 4: CA-2, RA-5
Manage device authentication and access control	· Managed remote access · Protected network integrity · Authenticated network devices	COBIT 2019: APO 13.01, DSS 01.04 COBIT 2019: DSS 01.05, 05.02 CIS: 9, 14, 15, 18 NIST 800-37 Rev 2: Task P-11 COBIT 2019: DSS 05.04, 05.10, 06.10 CIS: 16 NIST 800-53 Rev 4: AC-17, AC-18, IA-3, SC-40, SC-41
Network Defense	· Protected communication and control networks	COBIT 2019: DSS 05.02, APO 13.01 CIS: 8, 9, 12, 14, 15 NIST 800-37 Rev 2: Task R-2 NIST 800-53 Rev 4: PE-9, SC-8, SC-10, SC-41
Continuous monitoring of network behavior	· Monitored network for potential cyber incidents · Periodic network vulnerability scan	COBIT 2019: DSS 01.03, 03.05, 05.07 CIS: 1, 7, 8, 9, 12, 14, 15, 16 COBIT 2019: BAI 03.01, DSS 05.01 CIS: 3, 20 NIST 800-37 Rev 2: Task S-5 NIST 800-53 Rev 4: CA-7, SI-4
Incident response and recovery	· Incident response plan · Recovery plan	COBIT 2019: APO 12.06, BAI 01.10 DSS 01.03, 02.02, 03.04 CIS: 19 NIST 800-37 Rev 2: Task A-5 COBIT 2019: APO 12.06, DSS 02.05, 03.04 CIS: 10

Information Domain

The *Information Domain* includes the data that is either transmitted, processed, or stored. Depending on its purpose, it may be presented on various forms: plain, compressed, encrypted, digital, or analog. The four critical security requirements of the information domain are as follows:

1. **Data Protection:** Entails the provision to protect the confidentiality and integrity of information that are critical to the organization.

2. **Data Availability:** The availability of information is an important factor in day-to-day operations of an enterprise and thereby, should always be enabled.
3. **Data Backup:** Demands that provisions must be in place for data to be stored, monitored, reviewed, and restored whenever necessary.
4. **Manage Data Assets:** The management of data assets must include the policy to store, dispose, share, transmit and destroy information as needed.

The mapping of the requirements and controls with the frameworks and standards for the information domain is depicted in Table 5.

Table 5. The information domain requirements and controls

Requirements	Controls	Frameworks and Standards
Data protection	· Stored data protection mechanisms · Transmitted data protection mechanism · Data leak prevention mechanism	COBIT 2019: APO 01.06, BAI 02.01, 06.01 CIS: 13 COBIT 2019: APO 01.06, DSS 05.02 06.06 CIS: 5, 13, 14, 15 COBIT 2019: APO 01.06, BAI 04.04 CIS: 1, 2, 13, 16 NIST 800-37 Rev 2: Task P-10 NIST 800-53 Rev 4: AC-21, MP-2, MP-4, MP-6, MP-7, SC-8
Data availability	· Mechanism to ensure data availability	COBIT 2019: APO 13.01, BAI 04.04 CIS: 1, 2, 13 NIST 800-37 Rev 2: Task P-11 NIST 800-53 Rev 4: SC-5, SC-6
Data backup	· Process for maintaining and testing data backup	COBIT 2019: APO 13.01, DSS 01.01, 04.07 CIS: 10 NIST 800-37 Rev 2: Task P-13 NIST 800-53 Rev 4: CP-6, CP-9, MP-4
Manage data assets	· Managed data repository, asset removal, transfer and disposition	COBIT 2019: BAI 09.03 CIS: 13, 14, 16 NIST 800-37 Rev 2: Task P-12 NIST 800-53 Rev 4: PE-19, SC-8

System and Application Domain

The *System and Application Domain* includes the software, categorized as either system or application. The system software manages the operations of the cyber devices and provides the platform for the application software to operate. Examples of system software are the various operating systems such as Mac OS, Windows, Linux, and Solaris. The application software performs specific tasks for the users. Examples of application software are database management systems, web browsers, image processing software, and other productivity software. The four critical security requirements of the system and application domain are as follows:

1. **Software Asset Management:** Entails the provision for the inventory, prioritization, proper utilization, legitimate acquisition, transfer, and disposal of software assets.
2. **Software Risk Assessment:** Requires the periodic vulnerability assessment and threat evaluation of software assets.
3. **Software and System Security:** Entails establishing security baseline and integrity checking of software assets.
4. **Protection Processes and Procedures:** Entails the provision for processes and procedures for software change/patch management, secure software and system development and maintenance of software/system audit log.

The mapping of the requirements and controls with the frameworks and standards for the system and application domain is depicted in Table 6.

Table 6. The system and application domain requirements and controls

Requirements	Controls	Frameworks and Standards
Software asset management	· Inventory of system and application software · Formal process of disposition, transfer, and removal of software assets · Process to prioritize software asset based on criticality and value to business	COBIT 2019: BAI 09.01, 09.02, 09.05 CIS: 2 NIST 800-37 Rev 2: Task P-10 COBIT 2019: BAI 09.01, 09.02 CIS: 2, 13 COBIT 2019: APO 03.03, 03.04 12.01 CIS: 4, 13, 14 NIST 800-53 Rev 4: AC-1, AC-3, CM-11, MA-1
Software risk assessment	· Software and system assessment for vulnerabilities · Identification and documentation of software and system threats	COBIT 2019: APO 12.01, 12.02, 12.03 CIS: 3 NIST 800-37 Rev 2: Task R-2 COBIT 2019: APO 12.01, 12.02, 12.03 CIS: 3, 4, 18 NIST 800-53 Rev 4: CA-8, PL-2, SI-4
Software and system security	· Software and system integrity checking mechanism · Established and documented system and software baseline configuration	COBIT 2019: APO 01.06, BAI 06.01, DSS 06.02 CIS: 2, 3 COBIT 2019: BAI 10.01, 10.02, 10.03 CIS: 3, 9, 11, 12, 14, 16 NIST 800-37 Rev 2: Task P-4 NIST 800-53 Rev 4: AC-20, CM-10, SI-7
Protection processes and procedures	· Implementation of a secure system and software development life cycle · Process for configuration change control · Maintained and documented software and system audit/log records	COBIT 2019: APO 13.01, BAI 03.01, 03.02, 03.03 CIS: 18 COBIT 2019: BAI 01.06, 06.01 CIS: 3, 11 COBIT 2019: APO 11.04, BAI 03.05, DSS 05.04, 05.07 CIS: 6 NIST 800-37 Rev 2: Task C-2 NIST 800-53 Rev 4: AU-1, AU-2, AU-3, AU-4, AU-9

FUTURE RESEARCH DIRECTIONS

The complexity of the cyber threat and risk landscape portends the difficulty of developing and implementing an audit model that is robust, efficient, and adaptable to the rapid changes and advancements in cyber technologies. Adherence to established standards and frameworks provides guidelines and best practices with which the cybersecurity audit process could depend on. However, there are issues related to the process that remain unresolved or in need of some improvement. In this regard, the authors propose that following research directions:

- Investigate the use of blockchain technology to promote the validation and verification of internal controls;
- Design and develop digital transactions that are recorded on a digital and distributed ledger;
- Develop and implement metrics for cybersecurity audit; and
- Develop and implement a process for mapping cybersecurity controls with regulatory compliance.

CONCLUSION

The integration of cyber infrastructure into the enterprise compels organizations to judiciously build and develop a sound organizational culture on cybersecurity and a set of mechanisms to defend against cyberattacks. To this end, an organization must enable an independent entity with an oversight function to ensure that the cyber related activities are securely performed, and information resources are protected.

This article presents three risk mitigation defenses suggested by the Institute of Internal Auditors, which include suggestions for establishing appropriate positions and policies to address cyber risks, along with regular independent evaluations by internal auditors. To allow for even greater independence, the AICPA provides a reporting framework in which external Certified Public Accountants can be engaged to conduct a cybersecurity risk management examination. Any system of attestation requires an appropriate set of audit objectives upon which to base the evaluation. This research considers criteria for the assessment of cybersecurity objectives that were created by cybersecurity auditing standards and frameworks from four prominent authoritative bodies. It posits a cyber infrastructure that is composed of five domains and the cybersecurity requirements of each domain. Subsequently, internal controls are suggested to satisfy the cybersecurity requirements and mapped to the auditing standards and frameworks that cover the Risk Management Framework (RMF). Lastly, the article illustrates the invaluable benefit of using the standards and frameworks towards the development and implementation of internal controls for cybersecurity.

KEY TERMS AND DEFINITIONS

Audit Committee: A committee composed of outside members of a company’s board of directors, that is responsible for oversight involving a company’s internal controls and information reporting.

Blockchain: A digital register or ledger which embodies a permanent, time stamped, and cryptographically validated record of transactions.

Cyber Infrastructure: A collection of information technology systems and software, physical and information assets, processes, and people that enables an organization to efficiently and securely function on cyberspace.

Cybersecurity: A set of processes, practices, and technologies designed to protect, on the realm of cyberspace, the three tenets of information security: confidentiality, integrity, and availability.

Frameworks: A grouping of rules and related concepts into a logical approach that can be used to identify complex problems and decide upon appropriate courses of action to address them.

Internal Audit: A group of professionals who work within an organization to perform an independent appraisal activity to achieve efficiency and effectiveness in regard to both operating activities and information reporting.

Regulatory Compliance: The state of being in conformance to the requirements of a relevant law, policy, or regulation.

Security Metric: A quantitative, repeatable, accurate, and scalable measurement of an organization’s security posture.

Security Monitoring: A process of data collection, analysis, and detection with the goal of proactively securing an organization.

Standards: A set of rules that can be monitored for compliance by a specialized field’s authoritative bodies and related professionals.

Threat and Risk Assessment Using Continuous Logic

INTRODUCTION

The chapter presents a method to help assessing threats and their associated risks. Threat and Risk Assessment encompass a wide area, ranging from building construction to network and computer security through automotive design and construction, and many others such as Supervisory Control And Data Acquisition (SCADA), Energy Management System (EMS) systems among others, many of them closely associated with computer and networks systems.

Assessing threats and the risks associated to them implies several tasks such as identifying threat and risks, detecting them and their level of danger to a particular organization cybersecurity system, as well as to decide what to do with a specific threat, the costs of prevention or correction, the consequences of the actual risks occurring or, alternatively, not paying any attention to them, disregarding them.

Properly identifying, recognizing, making out a possible threat is the first step in this process; consequently, to have a list of characteristics, traits, attributes or requirements can be of help in that task. Therefore, it is necessary in first place to clearly define the set of requirements that can be of use in identifying threats and their related risks. Second, it is important to have a method that using those requirements eases the building of a model that assist people in charge with the job of assessing threats and risks in order to make well informed decisions on the matter.

The method proposed here is aimed at giving help in the area of cybersecurity and it is based on the Framework for Improving Critical Infrastructure Cyber security developed by the National Institute of Standards and Technology (NIST). The proposal integrates this framework with a quantitative method based on the use of a Continuous Logic, the Logic Scoring of Preference (LSP) method. LSP is a method suitable for decision making that provides the guidelines to produce a model/tool to assist the expert in the process of assessing how much a product or system satisfy a number of requirements, in this case associated to the identification, protection, detection, response and recovery of threat and risks in an organization. More specifically, the proposal is aimed to supplement steps 3 to 5 in the NIST program (NIST, 2018) with the necessary activities to develop a quantitative LSP model for assessing threat and risks in an organization. Therefore starting from a set of requirements taken from the NIST Framework, and applying the LSP method, a decision model can be developed. The resulting model can be used as an effective tool to assist professionals in the process of assessing potential threats and risks involved in any kind of organization, be it industrial, service, utilities, etc., providing a global indicator as well as a set of partial indicators, for each system under evaluation. These indicators are values in the interval [0; 100]; the global indicator represents the stage in which a system under evaluation is with respect to

DOI: 10.4018/978-1-7998-3473-1.ch083

the whole set of critical threat and risk requirements identified and, in the case of the partial indicators, to cohesive subgroups of requirements.

BACKGROUND

The next two subsections discuss related work on threat and risk assessment and introduce some concepts of the LSP method necessary to understand the rest of the work.

Threat and Risks Assessment

Threat and Risk Assessment is part of an ongoing process of identifying, assessing, and responding to risk. Threat and Risk Assessment in cyber security contexts is becoming more and more a concern for organizations of any kind, i.e. industrial, utilities, service oriented, etc., since computers and networks have penetrated nearly every activity. Organizations increasingly have the need to assess the potential threats and the risks involved in their processes and infrastructures. Not only commercial and government institutions but also utilities are aware of the potential threats to their infrastructures. Many open source and proprietary methods exist today to perform a risk and threat assessment, some focused on specific types of risk and some focused on specific business sectors. Of course the problem of threat and risk assessment is also considered in settings where security is a concern in a wider sense, for instance the threats and risks confronted in cyber terrorism, cyber war, and other similar scenarios; an overview of this can be found in Lewis, J. A. (2002). The threats and risks involved in unmanned aerial vehicles (UAVs) are also considered in Hartmann, K., Steup, C. (2013). In Ciapessoni, E. et al. (2018) the authors developed a method based on probabilities considering that threats can go from natural disasters to deliberate acts of sabotage.

There are also US patents on the subject such as Magdych et al. (2003), and Kelley, J. D., Lahann, J. S., Mackey II, D. H. (2006).

In Cherdantseva, Y. et al. (2016) there is a review of Threat and Risk assessment methods for Supervisory Control And Data Acquisition (SCADA) systems of great size and scope. It must be considered that SCADA systems are prone to attacks that can have serious consequences, e.g. Stuxnet malware (Zetter, K. 2019). Also Bayne, J. (2002) furnishes an overview of the whole process of Threat and Risk Assessment. There are also guides to risk management such as ISO 31000 (2018).

There is an extensive literature on security and network structure concerning smart grid environments, e.g. a Threat and Risk Assessment methodology, presented in Smith P. (AIT), Editor. (n.d.), where a “threat identification approach, based on attack graphs” is proposed. They use *Semantic Threat Graphs* (STGs) as “a tool to precisely determine the necessary countermeasures for the identified threats”.

Also the European Network and Information Security Agency (ENISA) analyzes in ENISA (2010) the future risks in a scenario of future air travel, where Internet of Things (IoT) and Radio Frequency Identification (RFID) technologies are used. The methodology employed is based on the standard ISO/IEC 27005:2008 Information technology — Security techniques — Information Security Risk Management. A very detailed “Vulnerabilities and Threats List” has been developed. A “Risk Identification and Assessment” is considered based on three elements, i.e. $\text{Risk} = f(\text{Asset}, \text{Vulnerability}, \text{Threat})$. A spread sheet was elaborated as part of the development (ENISA, n.d.).

Webb, J., Ahmad, A., Maynard, S. B., & Shanks, G. (2014) posit that they have identified deficiencies in Information Security Risk Management (ISRM), so they propose a Situation Awareness (SA) for ISRM model.

The Logic Score of Preference (LSP) Method

The Logic Scoring of Preference (LSP) method (Dujmovic, J. J., 1996, 1997, 1997b, 2007, 2018) has been adopted in this work as an integral part of the proposed threat and risk assessment decision methodology. LSP is a method for the realization of complex criterion functions and their application in the area of decision, evaluation, optimization, comparison and selection of general complex systems.

Since it is a general decision and evaluation method, it can be applied to different scenarios, particularly to the processes involved in threat and risks evaluation and decision. Given that LSP is not a simple additive scoring method, it is especially useful where the use of complex *and/or* decisions is necessary.

As in many other methods, initially in LSP the user requirements must be clearly determined, i.e. the main attributes to be taken into consideration for the model under development, as well as their corresponding preference values must be defined. These are generally organized in the form of a hierarchical tree, where the leaves of the tree correspond to the attributes to be evaluated. These attributes are called *performance variables*. Each one of these variables is then mapped into an *elementary preference* by defining and applying the corresponding *elementary criterion*, as the schema on Figure 1 shows.

An elementary criterion is a function that transforms a performance variable (real value) into an elementary preference (value in the interval [0; 100]). An elementary preference represents the degree of fulfillment of a requirement, where 0 means that the requirement has not been fulfilled at all and 100 that it has been completely satisfied.

The elementary preferences, obtained from the transformation of each performance variable via their corresponding elementary criteria, are used as input to the LSP *Criterion Function* or *Aggregation Structure*, as Figure 1 shows. These preferences are iteratively aggregated until a single global indicator of the degree of fulfillment of the whole system requirements can be obtained. More specifically, the aggregation structure creation process starts by aggregating elementary preferences by means of a set of operators provided by the LSP method. Aggregating a set of elementary preferences means to replace a group of them by a single output preference, which is a partial indicator of the degree of satisfaction with respect to the group of aggregated preferences. These output preferences are then aggregated again until a single output global preference G_0 is obtained. During this process, not only the elementary and partial preferences must be aggregated but it is also necessary to take into account both the relative importance of each preference as well as the necessary logic relationship between them.

The calibration of the LSP Criterion Function represents the most complex phase in the whole process, since not only it is necessary to take into account the needs of end users but also to validate the model to preserve the representation condition, i.e. the behaviour of the measures in the model to be the same as the corresponding entities in the real world.

Once the calibration of the LSP Criterion Function has finished, the evaluation process of threat and risks can start. It means that the values corresponding to each of the performance variables of the system under evaluation must be collected and provided as input to the model to finally obtain a global performance indicator, corresponding to the degree of compliance to the threat and risks assessment requirements, as well as a series of partial indicators corresponding to each of the subcategories considered in the requirement tree.

Figure 1. An overview of the LSP method evaluation process

The numbers delivered by the model point up the degree of compliance of the security implementations as well as the likelihood of risks that the organization is under. Both the partial indicators as well as the global indicator will assist stakeholders –normally, the threat and risks assessment team– on making decisions about the assessment.

The NIST’s Framework for Improving Critical Infrastructure Cybersecurity

The Cybersecurity Enhancement Act of 2014 granted The National Institute of Standards and Technology with the “role of identifying and developing cybersecurity risk frameworks for voluntary use by critical infrastructure owners and operators.”. (NIST, 2018). The Framework was developed with cybersecurity for critical infrastructures in mind, but it can be used by institutions of any size, degree of risk or sophistication.

There are diverse standards, guidelines, and practices, referenced to by the Framework which allow the organizations to describe their current cybersecurity posture; depict their target state for cybersecurity; identify and prioritize opportunities for improvement within the context of a continuous and repeatable process; assess progress toward the target state and communicate among internal and external stakeholders about cybersecurity risk.

The framework can be used in different ways by organizations. A first direct application is to compare the organization’s current cybersecurity activities with those outlined in the Framework Core. In this way, executives can obtain a feedback about a fundamental question: “How are we doing?” and, consequently, strengthen their cybersecurity practices where and when deemed necessary.

The framework also provides a common language to communicate requirements among stakeholders responsible for the delivery of different services to an organization.

An important use of the framework is establishing or improving a cybersecurity program. In (NIST, 2018) a number of steps to create a new cybersecurity program or improve an existing one are given, namely

Step 1: *Prioritize and Scope*. The organization identifies its business/mission objectives and high-level organizational priorities. With this information, the organization makes strategic decisions regarding cybersecurity implementations and determines the scope of systems and assets that support the selected business line or process.

Step 2: *Orient*. Once the scope of the cybersecurity program has been determined for the business line or process, the organization identifies related systems and assets, regulatory requirements, and overall risk approach. The organization then consults sources to identify threats and vulnerabilities applicable to those systems and assets.

Step 3: *Create a Current Profile*. The organization develops a current profile by indicating which category and subcategory outcomes from the Framework Core are currently being achieved. If an outcome is partially achieved, noting this fact will help support subsequent steps by providing baseline information.

Step 4: *Conduct a Risk Assessment*. This assessment could be guided by the organization's overall risk management process or previous risk assessment activities. The organization analyzes the operational environment in order to discern the likelihood of a cybersecurity event and the impact that the event could have on the organization. It is important that organizations identify emerging risks and use cyber threat information from internal and external sources to gain a better understanding of the likelihood and impact of cybersecurity events.

Step 5: *Create a Target Profile*. The organization creates a Target Profile that focuses on the assessment of the Framework Categories and Subcategories describing the organization's desired cybersecurity outcomes. Organizations also may develop their own additional Categories and Subcategories to account for unique organizational risks. The organization may also consider influences and requirements of external stakeholders such as sector entities, customers, and business partners when creating a Target Profile. The Target Profile should appropriately reflect criteria within the target Implementation Tier.

Step 6: *Determine, Analyze, and Prioritize Gaps*. The organization compares the Current Profile and the Target Profile to determine gaps. Next, it creates a prioritized action plan to address gaps – reflecting mission drivers, costs and benefits, and risks – to achieve the outcomes in the Target Profile. The organization then determines resources, including funding and workforce, necessary to address the gaps. Using Profiles in this manner encourages the organization to make informed decisions about cybersecurity activities, supports risk management, and enables the organization to perform cost-effective, targeted improvements.

Step 7: *Implement Action Plan*. The organization determines which actions to take to address the gaps, if any, identified in the previous step and then adjusts its current cybersecurity practices in order to achieve the Target Profile. For further guidance, the Framework identifies example Informative References regarding the Categories and Subcategories, but organizations should determine which standards, guidelines, and practices, including those that are sector specific, work best for their needs.

Any or all of these steps should be repeated as needed to assess and improve cybersecurity in an organization.

The method proposed here is intended to be of help especially in steps 3 to 5. Building the requirement tree and the LSP Criterion Function provides the organization with a model that reflects the organization needs and the desired cybersecurity requirements, i.e. an ideal target profile. At the same time, its

application to the actual practices makes available a current profile and the possibility of assessing the potential risk, creating action plans and achieving new evaluations in a future.

THE THREAT AND RISKS ASSESMENT MODEL DEVELOPMENT PROCESS

As assessing the threats and the associated risks is of crucial importance to organizations, making the right decisions in that assessment is also important for those involved in the decisions. What are the possible threats?; have we identified all the possible threats?; what is the degree of danger of an identified threat?; can it safely be ignored, since the probability of its occurrence is very low and the cost of taken it in consideration is too high?; is the risk of a threat very low?; have the organization the means to recovery given the occurrence of a specific risk?. These and many more questions are confronted by that people concerned with threat and risk assessment. It is not easy to answer them without resorting to some kind of tools, to recognize possible threats and the risks involved and what to do about them.

Having this motivation in mind, the authors propose the adoption of the method presented here for the development of an assessment model, which is based on requirements taken from the Framework for Improving Critical Infrastructure Cybersecurity by the National Institute of Standards and Technology Version 1.1 (NIST, 2018), and the guidelines of the Logic Scoring of Preference (LSP) method, a soft computing method suitable to help in evaluation and decision making. The NIST Framework is used to identify the requirements associated to threats and risks identification, protection, detection, response and recovery, while the LSP method provides the activities and techniques for the development of a quantitative model built on the basis of NIST Framework requirements.

The following subsections describe the Threat and Risk Assessment model development process that can be adopted when conducting a risk assessment phase in a cybersecurity program.

Threat and Risks Assessment Requirements

An important point when building a model is determining the organization needs. In the first place, the organization must determine the scope of the systems to be evaluated since different business lines or processes within an organization may have different business needs and associated risk tolerances. The same occurs when using the NIST Framework: “To account for the unique cybersecurity needs of organizations, there are a wide variety of ways to use the Framework. The decision about how to apply it is left to the implementing organization.” (NIST, 2018, p. vi). Besides that, NIST establishes that “Because each organization’s risks, priorities, and systems are unique, the tools and methods used to achieve the outcomes described by the Framework will vary.” (NIST, 2018, p. 2). These considerations and other similar ones also apply to the Threat and Risk Assessment model presented here.

Therefore, the first activity when developing an assessment model will be to determine the user’s needs and build a requirement model. Also the LSP method prescribes it as the initial activity, resulting in a hierarchical structure named *requirement tree* as main artifact, which will hold all the non functional requirements, i.e. the characteristics, sub-characteristics and attributes considered for the evaluation process.

A computable characteristic is one that cannot be measured in a direct way and whose value is obtained from other sub-characteristics or attributes that define it, i.e. they represent high level abstraction concepts. A sub-characteristic is also a computable characteristic, while an attribute or performance variable corresponds to a leaf of the requirement tree and can be measured in a direct way or by applying a specific metric.

To develop the threat and risks requirement tree, the five Functions of the NIST Framework Core (NIST, 2019) (Identify, Protect, Detect, Respond, Recover) can be considered as the top level characteristics in the requirement tree. “The Framework Core then identifies underlying key Categories and Subcategories – which are discrete outcomes – for each Function, and matches them with example Informative References such as existing standards, guidelines, and practices for each Subcategory.” (NIST, 2018, p.3). The categories and subcategories mentioned above will form part of the tree as sub-characteristics or performance variables. They are presented in (NIST, 2018, p.3) in table format and have a hierarchical arrangement with four items (columns): Functions, Categories, Subcategories and Informative References.

When adopting the whole NIST Framework Core, the resulting requirement tree model will consist of five Functions, twenty three Categories, one hundred and eight Subcategories, and five hundred and four Informative References, some of these last ones sometimes subdivided as well. Informative References seem to be the obvious choice for the performance variables in the requirement tree model. They could be a great help in assigning the values needed during the evaluation process.

Table 1 shows only the first two levels of the requirement model based on the Framework Core, while Table 2 shows all the requirements for the Category Communications (RC.CO), under the top level function RECOVER (RC). RC.CO contains three subcategories and seven Informative References that are as well subdivided, which for reasons of space are shown abbreviated.

Table 1. The first two levels in the Framework Core (NIST, 2019)

Function	Category

Elementary Criteria for the NIST Framework's Informative References

The next activity, prescribed by the LSP method, consists in the definition of an *Elementary Criterion* for each attribute in the requirement tree, in this case for each informative reference considered. An elementary criterion is a metric that returns a value in the Real interval [0; 100], which represents the fulfillment degree of the respective attribute in the system under evaluation and is referred to as *elementary preference*. During the evaluation process, the performance variables are transformed into elementary preferences by means of the application of their corresponding elementary criteria.

The definition of adequate elementary criteria is part of the work to be done when a model is developed. During the model calibration, sometimes elementary criteria must be modified if it proves necessary to fine-tune the model and preserve the representation condition.

During the process of elementary criteria definition, NIST Framework's Informative References must be taken into consideration. Many of the defined metrics will be direct, i.e. a resulting elementary preference takes the same value assigned to the corresponding performance variable, which sometimes can be obtained from expert's opinions or by simple observation. In other cases, an indirect metric will be necessary, e.g. the Informative Reference MEA03.02 (*IT compliance and support for business compliance with external laws and regulations*) shown in Table 2, which is part of the subcategory RC.CO-2 in COBIT 5, has two Activities. Activity 2 instructs to "Communicate new and changed requirements to all relevant personnel." (COBIT® 5, 2012). This implies that whoever is in charge should produce a list of new and changed requirements and a list of the relevant personnel to whom that should be communicated. Equation 1 shows the elementary criterion $MEA03.02_{A2}$ defined for Activity 2 as the mean value between the percentage of changed requirements effectively received by the relevant personnel and the percentage of new requirements effectively received by the relevant personnel. In Equation 1, $\#New$ denotes the total number of new requirements; $\#Changed$ the total number of changed requirements; NP the total number of relevant personnel to whom the new requirements should be communicated; $\#NewRec_i$ the total number of new requirements effectively received by the relevant personnel i . CP the total number of relevant personnel to whom the changed requirements should be communicated; $\#ChRec_i$ total number of changed requirements effectively received by the relevant personnel i .

$$MEA03.02_{A2} = \left(\frac{\sum_i^{NP} \#NewRec_i \times 100}{\#New} + \frac{\sum_i^{CP} \#ChRec_i \times 100}{\#Changed} \right) / 2 \quad (1)$$

To properly evaluate $MEA03.02_{A2}$, the threat and risks assessment team will have to gather the necessary data for applying the elementary criteria shown in Equation 1, i.e. consulting the appropriate personnel to verify whether the task prescribed in informative reference MEA03.02 has been completed, so as to obtain a correct estimation of the functioning of the involved personnel.

Aggregation of Preferences

Once the requirement tree has been constructed, a new activity can start: the construction of a quantitative threat and risk model. This model consists of an *aggregation structure* referred to as *LSP Criterion Function*, which is the result of a logic aggregation of preferences by means of an iterative process. The process starts with the aggregation of groups of related elementary preferences using GCD (Generalized Conjunction Disjunction) operators, provided by the LSP method, to obtain a group of partial preferences. These partial preferences are then iteratively aggregated by means of appropriated GCD operators until a single global indicator is finally obtained. Therefore, each partial indicator is the result of the aggregation of at least two partial or elementary preferences. In this way, step by step and applying this aggregation procedure, the partial indicators can be conveniently arranged to produce a single global indicator that represents the degree of fulfillment of all the requirements arranged into the requirement tree.

More specifically, to aggregate n elementary preferences $E_1, \dots, E_n$ in a single preference E_θ , i.e. the resulting preference E_θ interpreted as the percentage of satisfaction of the n requirements, is expressed by a function that has the following two properties:

1. The relative importance of each elementary preference E_i ($i = 1 \dots n$) is expressed by a weight W_i ,
2. $\min(E_1, \dots, E_n) \leq E_i \leq \max(E_1, \dots, E_n)$.

The GCD operators are obtained from the instantiation of the weighted power mean (Equation 2).

$$E(r) = (W_1 E_1^r + W_2 E_2^r + \dots + W_n E_n^r)^{1/r}, \quad (2)$$

where $0 < W_i < 100$, $0 \leq E_i \leq 100$, $i = 1, \dots, n$, $W_1 + \dots + W_n = 1$, $-\infty \leq r \leq +\infty$

The choice of r determines the location of $E(r)$. For $r = -\infty$ the weighted power mean reduces to the pure conjunction and for $r = +\infty$ to the pure disjunction, giving place to a Continuous Preference Logic. The range between pure conjunction and pure disjunction is usually covered by a sequence of equidistantly located GCD operators named: C, C++, C+, C+−, CA, C−+, C−, C−−, A, D−−, D−, D−+, DA, D+−, D+, D++, D. For a more detailed description of the technique see Dujmovic, J. J. (1997), Dujmovic, J. J. (2007), Dujmovic, J.J. (2018).

As a result of the application of the proposed method, a threat and risk model can be developed and adapted to the particular needs of a given organization. Seven GCD operators have been mainly employed in the aggregation structures shown in this work: CA, C+−, C−, C−, A, DA y D++. Typically, strong simultaneity operators are used for aggregating mandatory inputs, while weak simultaneity operators are adopted in presence of desirable attributes, meaning that the presence of a value of 0 (zero) in any of the inputs do not produce a zero in the output as it happens when a strong conjunction operator is applied. Therefore, in these cases, operators as C− or C−− can be adopted since they represent weak quasi-conjunctions. Operators A, DA and D++ are adopted in presence of optional attributes. In conclusion, the chosen operators should become more and more conjunctive as more mandatory the characteristics aggregated are.

Figure 2 shows a possible final aggregation of the five top level preferences resulting from the aggregation of the five top level categories (IDENTIFY (ID), PROTECT (PR), DETECT (DE), RESPOND (RS), and RECOVER (RC)). These five partial preferences have been aggregated by the operator CA since they all have been judged to be mandatory, meaning none of them should be with a very low value. Note that the rounded rectangles on the left of the figure depict the top level preferences, which serve as inputs to the operator CA; each of them represent the abstraction of a partial aggregation structure.

Figure 2. Aggregation structure for the five top level functions

The weights associated to each elementary preference should be assigned by the person or persons in charge of threat and risk decision making. They must reflect the importance that each preference has in the decision model being constructed. This is also illustrated by Figure 3 and Figure 4, where different parts of the whole aggregation structure built for the requirement tree of Table 2 are shown. In these figures, circles represent GCD operators, rectangles correspond to elementary preferences and the weights are shown over the edges (arrows). Rounded rectangles in light grey do not form part of LSP method notation, they have been introduced to indicate partial preferences corresponding to the abstraction of the aggregation of a set of preferences in the requirement tree.

On Figure 3 a partial aggregation structure for Function RECOVER (RC) is presented. Only the labels of the corresponding categories and subcategories are shown. No Informative References are displayed.

Figure 3. Partial aggregation structure for Function RECOVERY (RC)

Figure 4. Aggregation structure for Subcategory RC.CO 3, showing a Partial Absorption for COBIT 5

In Figure 4 the aggregation structure built for subcategory RC.CO 3 (*Recovery activities are communicated to internal and external stakeholders as well as executive and management teams*) is shown. Since aggregation structures allow discriminating between mandatory or non mandatory preferences, they permit to graduate how mandatory a given preference is considered by using the adequate GCD operators. However, sometimes there are features considered optional and whose absence should not penalize the result of the whole evaluation. In this situation a particular LSP structure, referred to as *partial absorption*, can be used. This structure is useful when aggregating a mandatory preference with optional preferences. Hence, if the mandatory preference is equal to zero the result of the partial absorption will be zero whatever the values of the optional preferences are. In any other case, the output corresponds to a mean value in a given range (see Dujmovic (1985) for more details on this). In Figure 4 a partial absorption structure can be seen. It corresponds to the aggregation of the Informative Reference for COBIT 5 APO 12.06 and it is shown in the rectangle with a dotted line. In this structure, both preferences “Act. 1” and “Act. 4” have been considered mandatory, while preferences “Act. 2” and “Act. 3” have been deemed optional.

SOLUTIONS AND RECOMMENDATIONS

There is a wide literature having to do with threat and risk assessment since the subject cuts across many and different areas. In multiple cases not only methodologies to use in the assessment but also procedures and techniques dealing with the decisions to be taken in the assessment process can be found. There is also a substantial amount of guidelines and recommendations such as the one being used here, namely NIST Framework, or COBIT, ISO/IEC, etc.; however, although they are very thorough, they are not enough by themselves to make assessment decisions and many of those guidelines are in need of a complementary model that helps in making decisions on the assessment. In this regard, the proposed method in this chapter can be used to assist in the process of building a model for the assessment of threat and risks and then forming the right decisions.

It is important to note that the method proposed here allows the development of a model, that can be adapted to specific needs and at the same time refined by adopting recommendations of other frameworks, not only from NIST. For example, standards such as COBIT, ISO/IEC, could also be used to refine the scope of the requirements considered for building the quantitative model. Therefore, the final aggregation structure can be adapted to different organization requirements and particular needs, as well as the weights and GCD operators employed can be changed to better reflect the necessities of an organization.

FUTURE RESEARCH DIRECTIONS

The requirements and the aggregation structure shown in this chapter can, of course, be changed to be adapted to different needs and demands that are specific to an organization or area. Therefore, the possibility of applying the proposed method to create a new model for other areas of cybersecurity, such as Supervisory Control And Data Acquisition (SCADA), systems that are widely used in assorted environments, or power distribution, construction, etc., should also be possible.

Therefore, potential avenues to explore in future research directions can be found in considering other requirements and in changing the resulting aggregation structure, by taking into account different proposals for cybersecurity according to new fields or different needs.

CONCLUSION

Assessing threats and risks implies making decisions, i.e. identifying threats, what is and what is not a threat, what is the potential of an identified threat, can it be avoided or not, what are the risks associated with a given threat, how can those risks be confronted, what are the costs of them and many other aspects have to be considered when evaluating threats and risks. Every one of these questions –and of course several other– require to figure out, to decide how important the threat is as well as its associated risk. So having methodologies and tools supporting these decisions is of outstanding significance.

Every human organization is prone to be subject to threats and risks and suffer their consequences. Having a flexible and reliable method that help in identifying and making right decisions about threats and risks is of paramount importance for the organization.

The threat and risk assessment method proposed in the chapter can be of great help for those people whose task in an organization is to assess the possible threats and risks confronted by their institution. The method presented makes use of a list of requirements. These requirements are of help in identifying the threats and risks that are likely to be faced up to by an organization dealing with cybersecurity. So this list of requirements is crucial and should be taken into consideration when building a method that can be of help in recognizing possible threats and the risks to be come up against by a cybersecurity installation. The proposal presented has considered the requirements taken from the Framework for Improving Critical Infrastructure Cybersecurity of the National Institute of Standards and Technology. (NIST, 2018). As part of the proposed method, these requirements have been used as input for building a quantitative model by following the directions given by the Logic Score of Preference (LSP) method, a method based on a continuous logic for the evaluation and comparison of complex systems. The model resulting from the integration of the NIST framework and the LSP method returns a series of quantitative indicators that are suitable for discerning and detecting security flaws at different levels, therefore providing insight for the decision making processes involved in determining the possible actions to be done to improve whatever would be necessary in the security and possible mitigation of threats and their associated risks.

The combination of the NIST Framework with the LSP method provides a powerful tool to help in the assessment of the current status of the organization and also a starting point for adopting a decision on the course of action to be taken.

KEY TERMS AND DEFINITIONS

Continuous Logic: A logic whose truth values can take continuous values in a given range (i.e. [0, 1], [0, 100]) instead of values like Truth or False.

Decision Method: A procedure, technique or planned way of arriving to a decision. Normally it could be said the decision is the process of making up one's mind. There are several decision methods ranging from very simple ones to more formal or axiomatic methods.

Decision Theory: The study of choices that a given agent can take.

Risk Assessment: Documenting the evaluation done of the possibility of occurrence of a risk as well as the damage associated and the measures to avoid it or at least mitigate the outcomes from the risk. Closely related with Risk Management.

Risk Management: Identify, evaluate, and assign priority to the potential risks with the goal of defining the methods, resources to minimize or mitigate the outcomes from the risk. Closely related with Risk Assessment.

Threat and Risk Assessment: Assessing risks is closely associated with a corresponding threat. Nearly any human endeavour has a potential threat and a risk correlated with it. Assessing both is mandatory in some areas, e.g. building construction, country security, network security, etc.

Threat Assessment: The manner of devising the possibility and importance of a potential threat.

Phishing Attacks in Mobile Platforms

INTRODUCTION

Mobile phones are mainly targeted by malware and they can also be used in botnets. Mobile devices are equipped with high – end, power-intensive resources with more memory, and variety of sensors. These are mainly used to provide a majestic, rich and for a sophisticated purpose. As far as Windows and Mac dominate the laptop world, where Apple and Android rule the smartphone and the tablet universe. Mobile apps were offered for the general productivity and for information retrieval which includes email, calendar, contacts, messages, and weather information. Now a day's mobile phones are also targeted by phishing attacks. So we can't say that mobile phones are not only used to make calls. We can say that mobile phones are a small computer. Smartphones are mainly used for social media which usually means to affect the bottom line security.

In mobile devices, user interfaces are constrained in a very small screen. In mobile operating systems, there is a lack of secure application identity indicators. The end user definitely can't tell what the website he/she is interacting with most of the end users i.e. 60% of mobile users will enter a password at least twice a day. By launching an application stored through app store phishing application can be done. Most of the phishing applications are launched with the help of the Android app store. By reliving the sensitive information, the attacker can easily hack the details of the users. Trojan Activity should in a suitable way. This will direct the end user to make a mistake in the malicious application of a trusted one.

The goal behind phishing is data, money and personal information glomming through the fictitiously unauthentic website. The best strategy for eschewing the contact with the phishing web site is to detect authentic time malignant URL. Phishing websites can be tenacious on the substructure of their domains. They customarily are cognate to URL which needs to be registered (low-level domain and upper-level domain, path, query). Recently acquired status of intra-URL relationship is utilized to evaluate it utilizing distinctive properties extracted from words that compose a URL predicated on query data from sundry search engines such as Google and Yahoo.

Now a day the threat of phishing attacks on mobile computing platforms is getting incremented as many of the users use mobile phones to access the net banking, Gmail, Face book and some other application. MobiFish is automated bulwark scheme, where users no desideratum to make the final decision, but it is the users who conclusively abstract the phishing app. Authentically, they do not require to explicitly make the decision at all, since the only explication for the authenticate failure is a phishing attack. Here there is no desideratum of developer to design the browser UIs, MobiFish is compatible with all subsisting websites and apps. In this paper, we propose specialized form of phishing attacks which target

DOI: 10.4018/978-1-7998-3473-1.ch084

at the sedulous account registry function of mobile OSs. We employ the optical character apperception (OCR) technique to extract text from the screenshot of a authenticate interface, which achieves better performance on mobile phones than on PCs.

Due to the lack of secure identity indicators which means that an inter-application link could be subverted. Next, the user will be directed to the wrong target. In a direct phishing attack, the sender will have some malicious application which links the user to the spoofed screen instead of the real target application. We are in need to address the problem of phishing by implementing the Trojan which commits phishing via preinstalled mobile applications. In a man-in-the-middle attack, the sender will be benign, but some other malicious party intercepts the link and he/she will load a spoofed target application in the place of the target application.

Figure 1. Vulnerable areas in mobile business environment

Trojan activity is a kind of malicious type which can be implemented in the built-in application. The trojan activity asks the user to enter some data that will appear in the form of a popup dialog. This popup dialog will collect some sensitive information. After finishing these steps the details collected will send to the hacker. The most vulnerable activity is sending the smishing messages this is also one of the phishing techniques. For example, a person gets a message that he needs to enter the bank details to claim some prizes. Through this activity, the attacker will get the sensitive information from the user so he can easily hack the mobile.

The other ways to hack the mobile by using Wi-Fi phishing. Wi-Fi Phishing will occur when a person gets connected to the internet through hotspots. If it is wireless, then an attacker will use evil twin for eavesdropping. If it is wired, then the attacker will use Starbucks for hacking the information. To overcome this, we can move to content-based filtering. It will have a set of rules which can easily predict the suspect the phishing contents.

Websites and mobile applications which commonly link the user to the social network which has password protected facility and obviously, payment applications. After it will ask the user to reflexively enter their basic information for gaining the credentials of the user to perform a phishing attack. By

this analysis of common behavior, we could identify a number of new phishing attacks are performed against mobile platforms.

Mobile phishing is also dangerous due to some hardware limitations of the mobile devices and also, we can include mobile user habits. In this, we did a deep study on the security vulnerabilities (Niu 2008) which is caused by mobile phishing attacks, including the web page.

Figure 2. Types of phishing attack

Phishing attacks, the application of phishing attacks, and the account registry phishing attacks. Existing schemes which are designed for PCs which can't effectively address the various phishing attacks on mobile devices (Felt 2011). We propose MobiFish is a novel automated lightweight anti-phishing scheme (Anti-Phishing 2006) for the mobile platforms. MobiFish which verifies the validity of the web pages, applications, and persistent accounts by comparing it with the actual identity to the spoofed identity.

The aim of Phishing attacks is to steal private information such as usernames, passwords, and credit card details by the method of impersonating a legitimate entity. Most of the security researchers have been proposed many anti-phishing schemes, the threat of phishing attacks is not reduced. On the other hand, lots of the phishing sites were expired and revived rapidly. By the other side, Phishing attackers are doing an extraordinary job for improving their techniques so that their new attacks are able to overcome the existing anti-phishing tools (Carnor 2007). Mobile phishing (Micro 2012) is an upcoming threat that targeting the mobile users of financial institutions, online shoppers, and mainly on the social networking companies.

Due to the hardware limitations, such as the small screen size and the inconvenience of user input and application switching and mainly on the lack of identity indicators, mobile user habits and preferences, etc... Mostly all phishing attacks on mobiles are in the form of bogus websites (i.e. Malicious sites). Nowadays browsers are the powerful tool which gives them enough to support for all kinds of Internet

services, and the people who are accustomed to online banking, online shopping, online socializing, etc. Users are being requested to provide the personal information, and of course providing private information and credentials to websites. Through this information, an attacker can easily hack the information and perform some unwanted matters.

Phishing detection schemes can be hardly divided into two categories: heuristics-based schemes and blacklist based schemes. Blacklist-based schemes will be able to detect only those phishing sites which are listed in the blacklist and mainly it can't detect the zero-day phishing attacks such as those that have only appeared for days or for an hour. It is true that new phishing sites will already steal the user credentials or have expired before being added into the blacklist. Heuristics-based schemes largely depend on features extracted from URL and HTML source code; it is also based on the other techniques such as machine learning which is used to determine the validity.

To reduce Phishing attacks there are some security concerns for the fake mobile applications. It will reduce the phishing attacks on the mobile platforms. The first security is that the users must download the official apps from app stores. The user should be aware of clicking the unknown links. Next, the users must use only safer browsers. Safer browsers which contain the security features and it also safeguard the users by eliminating the malicious and phishing sites for the security purpose. It is difficult to see the URLs in a complete manner. To recover from this bookmarking is a perfect solution to preserve the users landing on unwanted sites.

The forthcoming approach is by controlling the app stores. Vendors must keep eyes on developers before they upload their app to the public. Many security concerns have provided the anti-virus programs for the personal computers to avoid the malicious activities using some apps (e.g. COMODO). Next, by using the identity indicator, we can remove the header. The header is removable because the mobile screen size is small. Mobile devices have small screens, so users are unable to see the entire URLs; this will lead to the possible phishing attacks. This paper gives the clear overview of various types of mobile phishing attacks in the mobile platforms and it also discusses some mitigation approaches and security concerns. Users must be more careful while downloading apps and when they run on their devices.

DISCUSSIONS

AntiPhish is utilized to evade users from utilizing fraudulent web sites which in turn may lead to phishing attack. Here, AntiPhish traces the sensitive information to be filled by the user and alerts the user whenever he/she is endeavouring to apportion his/her information to a untrusted web site. The much efficacious elucidation for this is cultivating the users to approach only for trusted websites. However, this approach is fictitious. Anyhow, the user may get chicaned. Hence, it becomes obligatory for the associates to present such explications to surmount the quandary of phishing. Widely accepted alternatives are predicated on the creepy websites for the identification of “clones” and maintenance of records of phishing websites which are in hit list.

Web users have been suffering from phishing attacks since their first appearance in 2003. Researchers have proposed many solutions such as vigilant aegis and phishing detection to bulwark against phishing attacks. Mobile phishing assailment could additionally be in the form of Emails or Short Messaging Accommodations (SMS). Phishing emails (Bergholz 2010) customarily request users to click a link to a fictitiously unauthentic website where the user is prompted to enter authenticate credentials. In

additament, many phishing detection implements have been designed for phishing on PC web pages. Predicated on the methods utilized, they can be generally categorized into two groups: heuristics schemes and blacklist schemes. Heuristics schemes outperform blacklist schemes since they can deal with incipient phishing sites without having to wait for an update. Customarily, heuristics schemes for phishing detection utilize other techniques such as machine learning techniques and search engine.

Phishing websites, mainly utilized for e-banking accommodations, are very intricate and dynamic to be identified and relegated. Due to the involution of sundry ambiguities in the detection, certain crucial data mining techniques may prove an efficacious designates in keeping the e-commerce websites safe since it deals with considering sundry quality factors rather than exact values. An efficacious approach to surmount the fuzziness in the e-banking phishing website assessment is utilized a keenly intellective resilient and efficacious model for detecting e-banking phishing websites is put forth.

BACKGROUND

There is a great need to investigate issues related to credit cards misuses, bank accounts hacking, security threats, particularly loosing of an important credentials by Phishing attack. The major critical issue is stealing the account numbers and passwords stealing without the knowledge of the users, as trading over internet increasing day by day. Hence user must be aware of various phishing techniques that hackers use to gain the illegal access of important credentials while user accessing e-commerce-based services using their personal computers or mobile phones. The following are brief explanation about various phishing attack models.

SMS Phishing Attack

SMS phishing is an act of trying to acquire personal and financial information by sending SMS (instant Message or IM) containing a deceptive link. Most of the consumers access the internet through a mobile. The mobile user is not conditioned to received spam text message on their mobile. This SMS phishing attack is more effective since it is easy to set up and difficult to detect and stop before they cause harm. And also, most of the mobile anti-virus does not check the SMS.

Figure 3. SMS Phishing attack working process

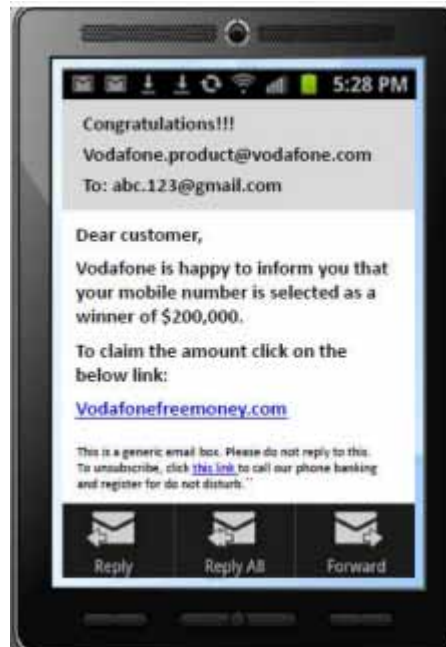

Figure 4. Sample mobile spam message

Mobile Spam

Unsolicited text/email message is sent to mobile device from known/unknown phone number or email IDs. Spam message contains advertisements or malicious links that can trick users to reveal confidential information. A significant amount of bandwidth is wasted by this spam message. This kind of the attack is done for financial gain.

Bluetooth and Wi-Fi Connection Attack

Mobile device pairing on an open connection using public Wi-Fi or any encrypted Wi-Fi routers which allows the attacker to eavesdrop and intercept data transmission using a technique such as;

- BlueSnarfing attack is the process of stealing the information via Bluetooth.
- Blue Bugging attack is the process of gaining control of the device via Bluetooth.

The sharing of data from malicious devices can infect and breach data on the recipient device.

Generally, browsers have many practical features and the convenient functions which are truncated during their adaptation to the hardware-constrained mobile platform. This will definitely result in an unpleasant experience for users. To improve this services most well-known enterprises have published the mobile applications (apps) for the major mobile platforms. This blows the new light on phishing scams, some of the phishing attackers develop fake apps and repackaging the legitimate apps. Next, they are uploading these phishing applications(apps) to unofficial app markets. By after using these apps the user's mobiles are getting attacked. The next process is when the attack succeeds, the user's credentials and information's will be sent to the phishing server.

Figure 5. Pairing mobile devices on open Bluetooth and Wi-Fi connection

Phishing web pages are easier to detect than the phishing apps because, for many web pages, he/she can be able to judge the destination of form-data from HTML source code i.e. Action attribute in the form tag. But if we think of mobile apps, there is no way to check whether the user credentials and also the information's are sent to the legitimate authentication server or to the attacker's server. Hence, phishing attacks on mobile phones are more complicated than which is performed on the PCs. Thus, we need to design effective mobile phishing Défense schemes for both the web pages and the applications.

Mobile Web Page Phishing Attack

Here we need to describe the three types of phishing attack models. First and Foremost, we are going to discuss the Mobile Web Page Phishing Attack. In PC browsers, the most widely applied method is Web page phishing detection. For the Web page phishing Detection, there are two existing methods used that is Blacklist-based matching and Heuristics-based.

The blacklist method is mainly used to search a suspicious site in a list of reported phishing sites. The blacklist can achieve higher accuracy for the cost of human verification but if it delays in updating the phishing sites it will definitely degrade its effectiveness. Blacklist-based methods cannot defend the new phishing sites which are not listed for example zero-day attacks. Next detection based method is Heuristic detection methods which are based upon the features which are extracted from URL and HTML source code this will often work with the help of search engine and machine learning techniques. These two features are summarized from previously reported phishing sites.

Moreover, a new phishing site may not contain these features at all because most of the features will only appear in some of the phishing samples. This defines that the most carefully constructed phishing sites which remove all of the suspicious features which could able to bypass the heuristics-based detections which means that the heuristics based approaches definitely can't achieve a 100% detection rate. Information which is extracted from HTML source code which may not be able to reflect the web page

Figure 6. comparison of OSR performance in mobile phone and PC

displayed to the user. This is the best way attackers can add some text, images which link into HTML source code with this they can also do some undesirable content which disappears from a webpage it by covering with other images and simply changing its size.

From this we can attackers can easily manipulate the word frequency, brand name, and company logo. This can be explained easily by real snapdeal. The attacker will copy the code of the original site and moved it to some websites. The attacker will also upload the image components to that website and he will change some other links to the corresponding places on our website. He will mainly focus on the form data submission URL. Moreover, the modified web page looks exactly the same as the official Snapdeal site. As a result, no user will suspect his validity without looking at its URL. Phishers or attackers can insert as many errors as needed into the HTML source code for obfuscating the conventional identity extractors. Mostly a large number of errors are extracted to convince the identity extractor the webpage which claims error instead of snapdeal. The webpage title will not be able to the user.

Mobile Application Phishing Attack

Applications which are based on Phishing attacks are quite uncommon in computers. Application-oriented phishing attacks are further classified into two types: First way is the most of the phishing applications will attempt to hijack the existing legitimate apps. Phishing apps will continuously perform the task polling and this will launch themselves so that they can detect the launch of the target apps. As a whole, the fake login interface layers will be overcome at the top of the real one. Next, the phishing app will appear as the target app. The users could not know what is happening when the window is in the switching process. We can solve this by checking the identity of the foreground app which is available in the task list.

The second way is that phishing app will directly show the original app. This will definitely occur when the mobile users download the fake apps from the unofficial app market sits. There are various methods to steal the user credentials but the essential attack pattern will be ended with the transmission of credentials a personal information to the attacker. By this, we can come to the conclusion both the runtime monitoring and blocking the communication of the suspicious apps which can effectively defeat the app phishing attacks.

Mobile Account Registry Phishing Attack

The Android system will provide a facility for accessing the centralized account registry and management function. This will allow the mobile users to log on to their online accounts (e.g. Instagram, Facebook, Twitter, etc.). So generally, this function will be called as Persistent Account Registry. Account Registry will be very convenient for the user who will not be bothered to enter their credentials and personal information each time for launching a social networking application. Mostly the mobiles are used for the personal purpose which can be accessed only by the mobile holding person. This can be guaranteed by simply setting by overall screen locking password. In the Android mobile, the persistent account registry can be done through Add account w option which is present in the Settings directory, this shows a list of applications which support persistent account registry.

Figure 7. persistent account registry function

Basically, any app can register itself to show up in the account list as a new account type. The application must contain an authentication service which is in need to be present in the AccountManagerService of the Android system. The persistent account registry is vulnerable to a phishing attack. The icon and label which are used in the main menu will not be the same which are displayed in the account list. So, the third-party app will register itself as another entity in the account list. This can be explained by an example where malicious game app which is pretending to be an application of a social networking company or financial institution. So, we can consider the app which is a fakeFacebook app in the account list. The GUI of that app will look as such like the original Facebookapp. When the user enters into the login page and he will enter all the credentials. Next, this credentials will be sent to the attacker or phisher. Here they have dealt with a fake login interface i.e.Appfish. Moreover, the account phishing attack is more stealthy.

MOTIVATION FOR ACCESSING THE PHISHING SITES

Phishers or attackers are using some fancy tactics to direct users to their phishing sites or applications, which masquerade as trustworthy entities. To solve this problem, we need to find the discrepancy between the identity it needs to be claimed and where the actual identity is placed. By having the HTML source code, we cannot find the claimed identity of a phishing site, so this is not only a reliable clue for identifying the phishing site. As an alternative, we should also focus on the screen which is presented to the user because users are directly spoofed by what they see. By using the existing anti-phishing schemes, we can't able to detect the app phishing attacks and account registry phishing attacks. Thus we are in a strong need to find an effective Défense scheme against the phishing attacks which are playing on the mobile platforms (Wu, 2016).

Extracting the Identity

The screen which is being presented to the mobile users should be the exact place of the claimed identity which is extracted from. The best way is to take a screenshot i.e. capturing the screen content. We can observe that most of the people will believe that screenshots can work well in identity extraction and verification.

The first way is that most of the login interfaces of the legitimate mobile sites and apps are very simple. The entire login page and the majority of the page can be captured in a screenshot. Another way is that the brand names and the company logo (identity) can be located at the apparent places in the login page this can be easily captured and extracted from the screenshot. Screenshots are useful for phishing detection in both web pages and applications. The source code of apps is not available. So, there is no possible way to acquire the content of an app login interface other than taking a screenshot. Next process is to obtain the claimed identity so for this, the OCR technique is utilized to convert the captured screenshot into text.

SLD is known as second-level domain where we can see the actual identity of the mobile page. Mostly famous enterprises will make their brand names as the second-level domain name (SLD) of their official websites. This can be explained with some example. Now let's take some banking sites. We can take Bank of America. Bank of America will be using the entire brand name as the second level domain name. Hardly in most of the cases, the brand names of the bank cannot be same as the second level domain name. The brand names will contain a symbol 'AT&T' where most of the content based schemes will be failing in this case due to the mismatch of the brand name 'AT&T'. In the second level domain, it will be showing this symbols as 'att' in legitimate URL most of the special symbols will not include in the domain name. This inconsistency can be solved by mapping it with the whitelist. Here the brand name 'AT&T' which will be mapped to the second level domain 'att' before the identity verification, the actual identity of mobile apps cannot be decided because of the unknown source code. This will enter all the information and credentials of the user. Suspicious apps will be cleared before the information of the users is allowed to transmit.

OCR Techniques

OCR is defined as the Optical character recognition (OCR). Optical character recognition which is the process where the mechanical and electronic conversion of an image will be converted to the machine-encoded text. Optical character recognition is the process which has been utilized to extract the text from

the text only logo. Goldfish is the process where it uses the optical character recognition which is to read the text from the web page especially from the company logo. We can definitely trust that Optical Character Recognition technique will be achieving the better performance on the mobile platforms because mobile is limited with a small screen size and with a relatively higher pixel density. Now we introduced the Optical Character recognition technique on the mobile platform. This technique will achieve the better performance and it will have a greater effect on the mobile phones by using some real experiments.

THE MOBIFISH SCHEME

MobiFish consists of three major components

1. WebFish
2. AppFish
3. AccountFish

These are designed to protect the mobile web pages, applications, and persistent accounts.

WebFish

In Web-scheme the defense scheme will be intimate with the URL loading. The first process is browser tries to load a webpage, firstly web fish will scan its URL. When a browser attempts to load a web page, WebFish first scans its URL to check whether the domain name is an IP address. Most of the Legitimate websites will always use their domain names as a verification of their identities. Attackers and phishers will be likely to use only an IP address for disguising their fake identities. WebFish will be containing the HTML source code of that loading page. Next, it will check if there is any form like the loading page. Phishing web pages must also need login pages with an input tag for entering the credentials and the personal details of the users and the user will submit the details to that phishing websites.

As the whole WebFish will be checking the existence of forms so that not every page need not go through the checking. Moreover, the identity extraction module will be not relying on any part of the HTML source code. If any of the forms is found WebFish will start to identify the extraction and verification. Firstly, it will extract the SecondLevelDomainName from the URL, which will be representing the actual identity of the site. Next SecondLevelDomainName will be indexed in the Mapping White-List (MWL). This will match the SecondLevelDomainName of the Brand name which gets recorded in the Mapping-White list. Next, the actual SecondLevelDomainName will be replaced by the corresponding brand name. On another side, the screenshot native function will be called to take a screenshot of the login page which will extract the text with the OCR tool. Here we need to note something if we take a screenshot the URL which is shown in the URL bar which will also get captured in the screenshot.

Before doing the identity verification the captured URL must be removed from the text because it will be containing the actual identity of the site. By seeing the existence of a URL bar which is captured in the screenshot will be determined by checking with the first line contains one of the top-level domain names such as gov, edu, com, and org. For speeding up the DetectionProcess There is a need to search for sensitive terms such as username, password and debit card, credit card number in the text. If nothing was found in that page it will generally use for the data input purposes and the page will be marked as a safe page. At last, the step is we need to search the SecondLevelDomainName in the text. If this is not found in it then it will be marked as a phishing site.

Figure 8. Workflow of Webfish

The AppFish Scheme

AppFish will maintain its database which is called as Suspicious App Set (SAS). Suspicious App set which will be containing the profiles of untrusted apps including the user ID (Uid), the launching time, and the screenshot text. If the user is getting suspected with some of the apps then they can name that app into SAS. The apps which are listed in the Suspicious App Set will be monitored by AppFish.

These apps can be classified into the two forms:

- Specified for a particular company
- Required user sign in.

First, they will be collecting the domain names of the collaborators. The domain names will get added into the SAS profile in advance. Owning multiple domains which will often happen to websites which needs an extra storage. This can be explained by taking the example of Facebook. Facebook will request the data from the domains like fbcdn.net. These sites will be used as a content delivery network(CDN). Most of the users will be uploading the photos on the facebook. Facebook can't store a largenumber of photos in facebook.com. So it will be using akamaihd.net. If the user needs to view a photo the request will be sent to the akamaihd server. Secondly, there are most apps where the users need not do login in browses and apps for news,music,maps,etc. Mostly in these cases, phishing attacks will not happen at all. Moreover, browsers i.e. webpage login will be protected by WebFish.

The AppFishdefense scheme works will be categorized in two phases:

- Launching phase
- Authentication phase

Figure 9. Workflow of appfish

In launching phase AppFish will be obtaining the name of each launching application then it will search for it in SAS. Once the logging process begins, the AppFish will be taking a screenshot of the logging process and it will be extracting the text by using the OCR tool. The text which contains the application userid and also it note the launching time when the user is logged into the profile. When the user has entered the credentials and the personal information. Next, he will click the sign in button so that the authentication phase begins. A trusted or legitimate applications (like Facebook and Twitter) will usually send the users credentials to a remote server for the authentication purpose through HttpGet/HttpPost. After the credentials get verified the applications will be loading the data belonging to that account. On the other side phishing apps can't load the original users data. Only one thing they can do is they can track the users that they have entered the wrong password. The user will suspect about the validity of the application, he/she will uninstall it. Hence, a phishing app is able to send out the user credentials only during the period from submission to uninstallation. Appfish will be monitoring the possible paths for a phishing app to transmit data to the outside world, which basically include HttpGet/HttpPost, socket, SMS and email (email which is also based upon the socket). If an application uses any of these things to send out an information, AppFish will be checking whether it is get suspected in SAS. If it is confirmed, then the HTTP connections (HttpGet/HttpPost) will get filtered while other communications (socket/SMS) are blocked.

The suspicious apps will be requested to connect with the URLs. AppFish will be ensuring that the SLD name which appears in the screenshot text and the affiliated domain names will be stored in the SAS profile. Moreover, socket and SMS functions will be blocked for a certain amount of time. This process could be enough for the user to notify the abnormality and the user will uninstall the malicious apps. Thus in phishing applications, they could not be able to send out credentials and the personal details before being removed by the user. Next, we need to search the second level domain name with the text which is being extracted from the login page. The reason, why we extracted the text instead of the application name, is, in phishing attacks which are based on the task interception i.e. hijacking, phishing app will be having the same app name as that of the phishing server, which will pop up a fake login page in some other entity. For an example, if the users download the phishing app named 'abc'. The user will download it because of its fancy operations and functions. Moreover, the malicious app will be pop up a fake Facebook login interface as soon as the original Facebook launches. Once the user gets spoofed,

the app “cdf” immediately sends the credentials to the phishing server “cdf.com”. In this example, the foreground i.e. Fake application name “cdf” is the same as the SecondLevelDomainName of phishing server, but the user cannot be about the Facebook phishing login interface.

The AccountFish Scheme

Due to the unlimited registry among the 3rd party apps will be possessing a huge threat to the privacy of the user and the account security. According to the survey of 2014, Yahoo stated that the average number of apps which is installed by an Android user is 95%. Users could not remember the app that has been installed so it is vulnerable to account registry phishing attacks. So they have proposed AccountFish to defend against the phishing attack which will mainly target at persistent accounts. The account registry phishing attacks can be categorized into three types. With the help of the malicious app will be appeared in the main menu and the account list. The first type is Attack; the malicious app will be appearing to be a different app of the targeted account. For example, a game app registers a into account. In the second type, B attack the malicious app will not appear in the main menu. Third type is C attack; the malicious app will directly showup the target app i.e. repackaged app that means they will be having the same application name as that which is shown in the main menu as the account name which appears in the account list.

Figure 10. Workflow of Accountfish

Detection mechanism for the first type and second type phishing attacks which is used to compare the app name in the main menu and the account label in the account list. Malicious apps can be dynamically registered and it can change the account information. The accountfishscheme must be able to inspect the registration of accounts which are held during the runtime. This can only have accomplished by changing the Android source code. Here we can check with the app name and account label. whether these two things i.e. app name and the account label are inconsistent the app will be highly a malicious app. Still,

there are some legitimate apps where their account labels are not exactly the same as the corresponding app names. This problem can be solved by using an account mapping whitelist (AMWL) which contains all the inconsistent legitimate apps. Suspicious Apps for suspicious apps which are not available in the whitelist, a warning will be contained for that app and the account names will be provided instantly. The apps which are being presented in the AMWL and those apps which are having consistent names will go for further checks. Type C Attack which is similar to AppFish, the decision cannot be made until the transmission of credentials happens over the apps for the AccountFish, the screenshot is unnecessary for the 3rd party apps so that account login interface cannot be hacked.

Another Hacking Scheme

Since 2003 web users are suffering from phishing attacks. Till now many types of research have been proposed many solutions.

- i) Alert protection
- ii) Phishing detection

First, we can see about the alert protection. The alert notification which is a simple notification which is used when the end user needs to enter his/her sensitive information. Antiphishing technique which was proposed by Kid. Antiphishing is a method which will detect the sensitive information of the end user. This method will warn the end user when he tries to give the information to the website which seems to be untrusted. Moreover, this scheme will not automatically check and detect the phishing attacks. The end user needs to judge selfly after they warned. More detection tools which have been designed for phishing attacks for the PC web pages. As we seen earlier it has been classified into two groups:

- Heuristics schemes
- Blacklist schemes

Heuristics schemes will overcome the blacklist schemes because they will deal with the new phishing sites. Mostly heuristics schemes for the phishing detection will utilize the machine learning techniques and search engine. The next approach is CANTINA. CANTINA which is a content-based approach for detecting the phishing websites, and also it adopts TF-IDF information retrieval algorithms.

Next Garera who proposed a heuristics based scheme which is used to identify the several generic features of phishing URLs and these features will be used in a logistic regression classifier. CANTINA method which is used for a comprehensive feature-based solution for the web page phishing which used to combine the machine learning and search engine techniques. HTML source code could not be trusted because it may not reflect the actual content to the end user.

Most of the phishing sites look very identical which are very similar to authentic sites.

Spoof Guard is a method which uses URLs, images, links and domain names. These are used to check the similarity between the present page and the page which is stored previously. Another method is PhishZoo. Phish Zoo which uses the profiles of the trusted websites appearances which are built with fuzzy hashing techniques. These are used to detect the phishing attack. PhishZoo will make the profiles of sites. This profile will consist of fuzzy hashes of common elements for example URL, frequently used text, HTML codes, images, etc. These are the common things which are commonly related to the appearances of the sites. These will enhance the phishing detection scheme by adding the images

into the profiles by utilizing SIFT image matching algorithm. If it depends on the different approaches the phishing sites cannot detect the sites. Goldfish is a method where the OCR i.e. optical character recognition for the phishing detection in PC browsers. OCR is technique is used to extract the text from images which are found in web pages (e.g., the logo of the company). By using this it will be compared with the pranked domains from a google search.

MOBILE PHISHING DETECTION

The major threat for the mobile users is a mobile phishing attack. Here we mainly discussed the hardware constraints of mobile devices. Browsers are advised to be redesign to make the authenticity and the origin of the user to be apparent to the users. It is a tough job to add the more features to the mobile because of its small screen size. They proposed an identity bar will display an identity bar will show the domain name or foreground application of the web page. Another phishing defense technique which employs a trusted ad unified login for UI apps. ScreenPass which provides a trusted software keyboard. This will allows the end users to store their passwords domains together with their credentials. The OCR which is used to ensure about the passwords that are entered by the users will be done through the trusted software keyboard. There is another detection method where they will be using an attested login for the user credentials by the use of the certificate. This certificate will be holding both the software and the hardware credentials and This also needs the modifications for the client apps. However, a proxy service which is designed for performing anti-phishing filtering against the URLs, page content, or user context. This is a need to be downloaded and configured manually in the browser. Users must be able to authenticate the identity of the proxies because the attacker can also set up some fake proxies. This idea which is similar to Antiphishing. Antiphishing is a scheme where it will give the warning of credential rendering instead of phishing vulnerability. Another method is Trusted activity chains this is to protect the activities from spoofing preventions. It is the developer duty to annotate the chain of activities that should not be interrupted. This show that existing apps are not protected and the developers must take high responsibility in this area.

SOLUTION AND RECOMMENDATIONS

MobiFish can be defined as which is capable of defending against phishing attacks on mobile web pages, apps, and persistent accounts. The aim of the MobiFish is to solve the essential problem of identity masquerade without reliance on HTML source code, on the search engine and for the machine learning techniques. So, for this inconvenience, we can use the optical character recognition (OCR) technique to extract the text from the screenshot of a login interface. This will definitely achieve better performance on the mobile phones than on PCs. We could able to find the spoofed identity from the original text and the actual identity which from the URL of a web page or the remote server mainly for mobile apps. The two identities are different then it must send a warning message to the user. For the account registry phishing attacks, MobiFish will effectively detect all three variants from checking the consistency of account label to app name and the destination of credential transmission.

Hardware Limitation

Due to the small size of the mobile screens and limited computational power, browsers which are working in the mobile systems need to be removed or we can degrade some of the features to make more space for web contents and to maintain a smooth user experience (e.g. loading speed). Phishing web pages which could be detected and blocked on computer browsers which can still be accessible from the mobile browsers. In addition to this, the user interface which is designed for mobile browsers is also simplified, this simplified design could instead help the phishing sites to bypass user inspection. For accommodating the small phone screen size most of the mobile browsers need to remove the status bar and need to hide the URL bar when the web pages' finish loading.

When the loading process is being done, long URLs are discarded to fit the browser frame. There is a risk associated here for the user because the ability for reading and verifying the URLs is very critical for detecting the phishing attack. Since the ability to read and verify URLs is crucial in detecting phishing attacks and the partial URL which means especially a URL with only partial domain name displayed this will lead the user to the spoofed page this will increase the phishing attack. We can explain this by example, think now we are having the official website of "bank of India" which shows the URL bar with a partial domain name. This will definitely lead to a successful phishing attack. The legitimate users are convinced by the partial URL and they are ready to submit their credentials and personal information. Here the phishing attack will happen the user will think that URL will move to the `http://securebankofindia.com` will move to the "`https://secure.bankofindia.com.phishing.com`". This phishing attack would fail if the entire URL and the full domain name is displayed.

There are two possible ways, the first way is once the user can view the URL completely and another possible way to which the user could view the URL completely just by clicking the address bar and also by scrolling all the way to the end. The second way is to view the actual destination of a link, this can be done by holding the link for about two seconds. The destination URL which will display the domain name with many as 31 characters instead of showing the 19 characters in the URL bar.

Most of the legitimate sites, the domain names of the websites which can be easily mimicked by replacing the letters. This can be explained by distinguishing 'I' from the capital 'i' for example, it is hard to distinguish 'I' from the capital 'i' because mobile browsers will display both the characters in the vertical slash shape. For both the capital 'I' and capital 'i' together and also to find the small difference in height which is very difficult to discern by human eyes. So, for this kind of letter replacement phishing attacks both the attentive users and observant users who will always check the entire URL i.e. domain name which is likely to be fooled. Mostly the lack of identity indicator was another issue in the mobile phishing.

User Habits and Preferences

Mostly the user habits and the preferences will further increase the vulnerability to mobile phishing attacks. For the past few years' touchscreen smartphones are becoming more dominant in the mobile phone market. Moreover, by typing in a virtual keyboard is not that much easy as on a physical keyboard because of the inability of the lower input accuracy, particularly in the actions walking or sitting in a moving vehicle. Because of this reason, it is tempting to follow the links in web pages and e-mails rather than typing the links manually. The other factor is that on smartphones, switching over the applications and shifting to some other pages within a browser which is more complicated and dangerous than being performed on a PC. Phishing attacks can be succeeded because users will get trust and accustomed

to entering their personal information and credentials in the most familiar which has a repeated login interface. If users frequently check their legitimate links whose targets prompt them for private data of the user and they will be supplied the requested data.

FUTURE RESEARCH DIRECTIONS

Although traditional phishing attacks mainly rely on hacking the mobile environment, they focus mainly on taking advantage of the limited (or lack of) security in mobile devices. Several detection schemes are available for desktop and wired computers but they are not readily available across wireless and mobile devices. This is due to the limitations of mobile devices, namely power, processing, and storage. Implementing traditional anti-phishing solutions, such as machine learning approaches, in a mobile environment is inapplicable since some of these solutions are heavy in nature. Anti-phishing solutions in a mobile environment should take advantage of the high predictive accuracy of machine learning approaches and reduce high overhead associated with such approaches by building a distributed client-server framework.

CONCLUSION

In this, we went through the issue which is presented in the mobile phishing detection. Here we proposed MobiFish. MobiFish is a novel automated phishing defense scheme for the mobile platform. Hence we identified the inefficiency of the heuristics-based anti-phishing schemes which highly rely on the HTML source code of web pages. Recent years have witnessed the incrementing threat of phishing attacks on mobile computing platforms. In this project we proposed MobiFish, a novel automated phishing bulwark scheme for mobile phones with Android OS. In this work first we identified the impuissances of the heuristics-predicated anti-phishing schemes that highly rely on the HTML source code of web pages. MobiFish solve this issue by utilizing OCR that accurately extracts text from the screenshot of the authenticate page so that the claimed identity can be verified. Compared to subsisting anti-phishing schemes, MobiFish is lightweight as it works without utilizing external search engines or machine learning techniques. MobiFish can additionally detect account phishing attacks. We are implementing MobiFish on Smartphone running the Android OS. MobiFish resolves these issue by using OCR. OCR (optical character recognition) where we can accurately extract the text from the screenshot of the login interface. From this, we can be verified with the claimed identity. When we compare the MobiFish with the Existing OCR based anti-phishing schemes, MobiFish is considered to be the lightweight because it works with by using external search engines or the machine learning algorithms. MobiFish can also detect the app phishing attacks and account phishing attacks. In research perspective, the plan is to implement this proposed approach on Smartphones running with different Android OS. Further complexity of this proposed scheme needs to be analyzed with respect to performance and efficiency.

KEY TERMS AND DEFINITIONS

MWL: A whitelist is a list of e-mail addresses or domain names from which an electronic-mail blocking program will sanction messages to be received.

OCR: The fundamental process of OCR involves examining the text of a document and translating the characters into code that can be utilized for data processing.

SLD: A second-level domain is a categorical part of a website, page domain name or URL address that complements a top-level domain.

SMS: It is the most rudimental communications technology for mobile data transfer and is characterized by the exchange of short alphanumeric text messages between digital line and mobile contrivances.

URL: A uniform resource locator (URL) is the address of a resource on the Internet. A URL denotes the location of a resource as well as the protocol used to access it.

Blockchain Technology and Its Applications

7

Ting Wang*Indiana University South Bend, USA***Liguo Yu***Indiana University South Bend, USA***Yingmei Li***Harbin Normal University, China*

INTRODUCTION

The most volatile currency on financial market in the past several years is bitcoin for sure (Grinberg, 2012). A unique property of bitcoin is that it has no backup from central banks of any country. In addition, bitcoin is a decentralized currency system, where the transactions and the creation of new coins are done automatically following computer algorithms (Nakamoto, 2008). Nobody is sure about the future of bitcoin, because this really depends on government regulations, customer preference, technology evolutions, and alternative financial solutions. However, one of the key technologies under bitcoin currency—blockchain, will definitely be utilized in many fields because of its revolutionary data design, data recording, transaction execution, and transaction validation.

This paper describes the fundamentals of blockchain technology, including its data structure and transaction rules. In addition, this paper describes representative blockchain development platforms, the current and potential applications of blockchain and its broader impact on business and industry. The objective of this paper is to help readers understand one of the disruptive technologies that are transforming the business practice and reshaping the IT industry's landscape.

BACKGROUND

In January 2009, the first bitcoin transaction was successfully completed. In 2010, the first commercial bitcoin transaction was recorded (Morse, 2017). These events marked the beginning of a revolutionary electronic currency. In less than ten years, bitcoin has become the most influential cryptocurrency on the planet. Currently, there are over 200 thousand bitcoin transactions per day. Although this number is much smaller than the number of traditional financial transactions (such as credit card transactions) per day, it is drawing more and more attentions. In addition, other cryptocurrencies were created in the past years following the success of bitcoin.

The major impact of bitcoin might not be limited to financial industries. What is more revolutionary is the fundamental technology used to implement bitcoin—blockchain (Hayen, 2016). Businesses, governments, and institutions have realized the importance and potential applications of blockchain. Intense research and developments are being carried out in various fields. However, as with any other

DOI: 10.4018/978-1-7998-3473-1.ch085

emerging technology, while blockchain has certain strengths and can bring certain benefits, it also has weakness and can bring certain risks. Therefore, it is worth of studying this technology in detail before adopting it in business and applications.

TECHNOLOGY DESCRIPTION

Data Structure

Blockchain is a back-linked list structure that consists of individual blocks. Like any list structure, Blockchain has a head-block and an end-block. If the blockchain size is 1, the head-block is just the end-block. Also like other list structures, the new block is added to the end of the chain and becomes the new end-block. The back-linked list means that newly-added block is pointed (linked) to the old end-block. In this paper, we call the relationship between the newly-added block and the block it points to a child@parent relationship. Clearly, every block except the head-block has a parent.

The data fields of each block basically include three parts: a block ID, transaction data, and meta-data (Eyal et al., 2016). The meta-data field is also called the header of the block. It includes timestamp the block is created, its parent block ID, and other data items. The main purpose of having a parent block ID in meta-data is not just to provide a physical link between the child and the parent. The physical link can be implemented in many different ways, such as pointers. Instead, having a parent block ID provides a mechanism to demonstrate or validate the legitimacy of a block. Using an analogy in biology, this is like to say that someone carries its own DNA together with its parent's DNA so that it can claim (prove) to be the biological child of its parent. Figure 1 shows a general block chain structure.

Figure 1. A general blockchain data structure.

In blockchain, the close relation between a child-block and its parent-block is achieved using the cryptographic hash function. Like a regular hash function, a cryptographic hash function can map arbitrary size data to a fixed value as shown in Figure 2. In addition, a cryptographic hash function has

the following properties: (1) same inputs always generate the same hashed values; (2) technically, it is not possible to figure out the input given the hashed value; (3) technically, it is not possible to find two different inputs that will generate the same hashed value; and (4) slightly different inputs can generate dramatically different hashed values. These properties make cryptographic hash function an ideal candidate to generate the block ID field of each chain block. The detailed process will be described below.

Figure 2. Demonstration of a hash function (MD5).

To ensure the integrity of the transaction data, the cryptographic hash function could be applied on it to generate a transaction hash (value), which could also be saved in the meta-data field, as shown in Figure 1. The block ID can then be generated by applying the cryptographic hash function on the meta-data field, which contains timestamp, parent block ID (except for the head-block, which does not have a parent), the transaction hash, and other data items. Therefore, each block ID is genetically coded with its parent block ID, linking them together forming a close and verifiable relation.

The data structure and implementation of blockchain make it impossible to modify the transaction data of a block without modifying its transaction hash, its block ID, its child's block ID, and its grand-child's block ID, and so on and so forth. This kind of hashed-chain data structure makes the transactions (records) stored in blockchain tamper-proof or secure.

Data Distribution, Communication Protocol, and Verification Mechanism

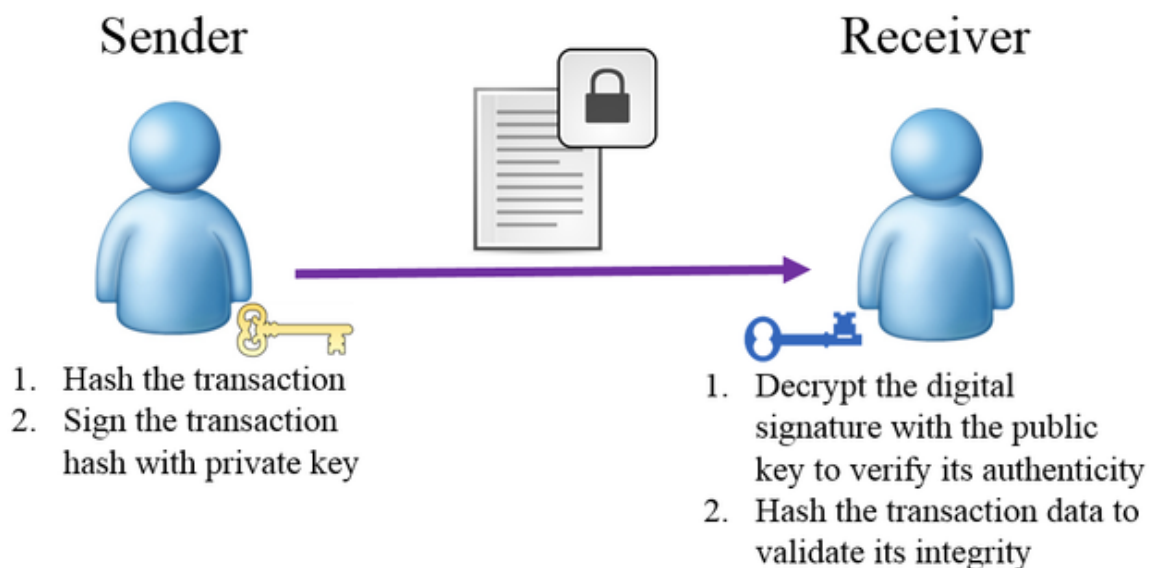

Unlike a traditional file or a traditional database, blockchain is stored in a distributed network (Croman et al., 2016). Usually, there is no central node that controls the network. Instead, all nodes are considered equal and have exactly the same blockchain data record. Decisions, such as overwrite a transaction or delete a block, can be made through a majority vote of the participating nodes.

Because blockchain is designed as a distributed and decentralized digital record storage, part or the entire copy of the blockchain is stored on each client's site. A reliable, fair, and convenient communication mechanism is needed to maintain the blockchain. One solution is to store a decentralized tracker, which contains the address of all current clients, in all sites. All trackers will be updated when new clients join the network. Communications among clients could be implemented with message passing or remote procedure call (Andrews, 1991).

When a new transaction needs to be recorded, a new block is created and added to the blockchain on one client site following the hashed-chain mechanism described in the previous subsection. The new block is then broadcast to the whole network so that all other clients on the network could validate the new block and add it to the chain.

The whole chain blocks are transparent to all clients, allowing anyone to verify the legitimacy of a transaction. This policy can be implemented with the public-key cryptography (Salomaa, 2013), where digital signature is used to prove the legitimacy of the transaction. Specifically, an authorized party signs (encrypts) the transaction with its own secret private key. The public key has been made available to all clients, allowing anyone to verify the authenticity of the transaction and validate the integrity of the transaction. Figure 3 shows the process to sign and validate a transaction using the public-key cryptography. Details about the blockchain transactions are given in the following subsections.

Figure 3. Sign and validate a transaction using public-key cryptography.

Transaction Execution

Many different types of transactions can be executed and recorded in a blockchain network. Examples of transaction types include record of e-commerce, package delivery, financial service, healthcare service, transportation service, etc. In most cases, each transaction is associated with two parties, such as a seller and a buyer, a payer and a payee, a service provider and a service receiver, and so on and so forth.

What is being transferred between the two parties can be virtualized as a token. Bitcoin is the best known example, where each bitcoin is an address (token). In fact, the bitcoin address is just an algorithm-

generated hash value, not a physical address. Other types of transactions could be modeled following similar mechanisms. For example, a product in an e-commerce transaction, a package in a delivery order, and a service in financial or healthcare sectors can all be virtualized as a token passing from one party to another party. Some other records, such as registration, identity, and certificate could also be modeled as a token, and anyone with a private key can claim to be the owner of the token.

When a transaction is conducted, the owner of the token needs to send the token to the receiver. This operation follows four steps.

1. Before the transaction, the token owner has a pair of keys (a private key and a public key) and the token receiver also has a pair of keys (a private key and a public key).
2. The receiver sends its hashed public key to the owner, which later will become the address of the new token.
3. The owner then creates a transaction message containing the following information: ID of the previous transaction where the token is saved; its own public key; its signature signed with its private key, the receiver's public key hash, and details of the transactions, such as amount in the case of currency. The general structure of a transaction message is shown in Figure 4.
4. The transaction message is then broadcast to the network, pending validation by other clients.

Figure 4. General structure of a transaction message.

Transaction Verification

Transaction verification in blockchain is carried out through looking up past transactions to ensure the validity of the old token and to validate the sender's ownership. Generally speaking, transaction verification follows four steps.

1. Once a responsible node receives a transaction message, it will use the public key embedded in the message to verify the signature, proving the integrity of the transaction, which means the message has not been tampered.
2. Then, the responsible node will use ID of the previous transaction listed in the message to search the blockchain list to identify the previous transaction and compare it with the new transaction.
3. Next, the responsible node will need to hash the public key provided by the sender and compare the hash value with the public key hash stored on previous transaction. If these two values are same, it proves the sender owns the token (public key hash listed on the previous transaction) and it is legitimate for the sender to pass the token to others. This process is illustrated in Figure 5.
4. After Steps 1 to 3 are successfully completed, the transaction message will be converted to a transaction record with an assigned transaction ID. The transaction record is written permanently into the block recognizing the value (status) and ownership of the new token.

Figure 5. Cross-check a new transaction message with its previous transaction record.

After the new token is passed to the new owner, the old token carries no values. In the case of bit-coin transaction, the remaining balance after a transaction will be carried on to another new token and assigned to the owner itself. Since the new owner's public key hash (token) is saved in the transaction, only the person having the corresponding private key can claim to be the owner of the token.

Blocks Creation

In applications with less frequency of transactions, a new block can be created and added to the block-chain for every transaction. This is a simple design for small applications. For applications with frequent and concurrent transactions, a block could be designed to store more than one transactions, and a new block is needed only if its parent block is “full of transactions”. There could be different mechanisms to define the “fullness” of a block. In Bitcoin, a new block is generated about every 10 minutes, which is controlled by some algorithms; all confirmed transactions within that 10 minutes period will be stored in the same block.

If more than one transactions need to be stored in a block, a binary tree is a best solution for large number of transactions, which can make it more efficient to search the transaction records and validate a new transaction. Because transactions need to be hashed to ensure their data integrity, Merkle tree could be used (Buchmann et al., 2008). Figure 6 shows the structure of a chain block with multiple transactions hashed as a Merkle tree.

To validate a transaction in a block as shown in Figure 6, a binary search can be conducted to locate the transaction and then validate the parent hash values, recursively. For example, to validate a transaction, say T_4 , we need Hash H_3 , Hash H_{12} , then we can carry out hash operations to validate Hash H_4 , Hash H_{34} , root hash, Block ID, and so on.

Figure 6. A chain block with multiple transactions hashed as a Merkle tree: *T* represents a transaction; *H* represents a hashed value.

PROTOCOLS AND PLATFORMS

Blockchain is a technology prototype. To implement blockchain, specific technology and protocols should be standardized. Many platforms have been established in the past 10 years. Among them, Bitcoin, Ethereum, and Hyperledger are considered outstanding, which are described below.

Bitcoin

Bitcoin is a blockchain protocol designed in 2008 and launched in 2009. It is open source software, implemented as an ad hoc decentralized network and messages are broadcast on a best effort basis. Bitcoin is now the world's largest digital currency trading system. Over 100 companies accept bitcoin payment, including *Subway*, *KFC Canada*, *Microsoft*, *Expedia*, and *Dish*.

Ethereum

Ethereum is an open-source distributed computing platform employing blockchain technology. This platform features smart contracts and decentralized applications. More than 100 companies, institutions, and organizations have joined the *Enterprise Ethereum Alliance* to define a standard blockchain protocol to govern the industry. These members include *Toyota*, *Samsung*, *Microsoft*, *Intel*, *J.P. Morgan*, *Merck*, *Deloitte*, *Accenture*, *MasterCard*, *Cisco*, and more.

Hyperledger

Hyperledger is an open source blockchain platform created in 2015 by the Linux Foundation. The objective of Hyperledger project is to provide a platform supporting the development of blockchain-based distributed ledgers. Supporting companies of the project include *Cisco, Hitachi, IBM, Intel, NEC, Red Hat, J.P. Morgan, SWIFT, Wells Fargo, Accenture*, and others. Currently, *IBM's* blockchain solutions are built on top of Hyperledger platform.

APPLICATIONS

As described in Section 2, the most important properties of the blockchain technology are the traceability and integrity of all records. These properties make blockchain a promising solution in financial services, healthcare services, identity services, delivery services, and so on. These potential applications are described below.

Financial Services

Traditionally, financial transactions are stored in database. With blockchain, any type of financial transaction, such as sale, purchase, receipt, and payment can all be recorded in blockchains (Peters & Panayi, 2016). This implementation will make it easy to avoid errors, resolve conflicts, and track every transaction. For example, the purchase and sell of a stock, mutual fund, and ETF can all be converted as blockchain transactions. *J.P. Morgan*, in partnership with *Royal Bank of Canada* and *Australia and New Zealand Banking Group*, has launched a new payment processing network using blockchain technology. Other global banks, including *UBS, Goldman Sachs*, and *Morgan Stanley*, are evaluating and optimistic about this technology.

International business, such as cross-border trading and cross-border payment, can be improved with blockchains (Guo & Liang, 2016). Traceable order status, delivery status, and payment status can reduce the complexity and improve the efficiencies of business operations. Other financial services that blockchain could be used include insurance claim processing, credit rating, and loan payment recording. *IBM* and *Accenture* are in leading positions in providing a broad range of blockchain-based financial services.

Charity, especially targeted donation is another area that blockchain can play an important role (Swan, 2015). Currently, if a donor wants to donate to a specific needed person through a philanthropic organization, it is not easy to verify the delivery of the money, especially if this is an anonymous donation. With blockchain, the transaction of the donation can be made traceable to the donor. Even for general donations, applying blockchain technology, we can make the distribution of donations more transparent to the public. *Alice* and *Giveth* are two blockchain-based charity and fundraising platforms that support traceable and transparent donations.

Identity Services

Currently, if you apply for a credit card online, file a tax return online, or conduct a financial transaction online, you will need to provide different kinds of data to prove your identity. With blockchain, a digital online ID could be created and stored in blockchain-based authentication services. The hashed online ID, just like bitcoin transactions, is transparent to all parties. But, only the one that possesses the private key

used to generate the online ID, can prove to be the owner (Shrier et al., 2016). *IBM* is currently working on this field. Many startups, including *civic*, have begun to provide secure, verified identity services.

For offline applications, blockchain could also be used to store IDs, such as driver's license and passport (Biggs, 2014). To create a digital driver's license or passport, a picture should be taken first. The owner then signs the digital passport or driver's license with a private key. The digital ID can be saved in a blockchain-based system. When an ID is needed offline, the owner can provide the private key to retrieve the ID online and show it to the interested officials. *Shocard*, a startup founded in 2015 and headquartered in Palo Alto, California, provides enterprise identity authentication services.

Intellectual Property and Physical Goods

Store the authorship and ownership of an intellectual property, such as patent, book, film, and music in a blockchain will make these information transparent to the public (Ha, 2016). Transfers of ownership can also be recorded. *Bernstein Technologies GmbH*, a German company based in Munich offers blockchain solutions for intellectual property management.

Certificate of luxury goods can also be stored in blockchain. The certificate can include detailed description of the item including pictures. It works like a digital ID of the luxury good (Fanning & Centers, 2016). *Everledger*, a London-based company, is an industry leader in this field. It has registered more than 1.6 million diamonds using blockchain.

Blockchain can also be used to trace the path of a physical good in the supply chain from producer to end consumer. The main purpose of this application is to protect the consumer from buying fake goods. This objective can be achieved through storing the product's auditable journey records from production to consumption. Recently, China's e-commerce giant *Alibaba* announced to create a blockchain-based food security system (Ngo, 2017).

Property Registration

Ownership of land, real estate, and vehicles are currently documented offline and kept in a centralized government agency or an organization. To verify or transfer the ownership is a tedious process. With the support of blockchain, these registrations can be made public available to allow a permitted party to access (Underwood, 2016). Storing registrations on the blockchain will make it impossible to forge a faked ownership. This practice can improve business efficiency, decrease operating cost, avoid personal lost, and increase trust. Some European countries, including Georgia, Sweden, and the Ukraine have begun to register land titles in blockchain. Other countries, such as Russia and America are testing this idea.

Package Delivery

Package tracking now days is available for some services within a carrier. However, cross-carrier and cross-border tracking is hard. Using blockchain, we can integrate individual centralized tracking systems, such as FedEx, UPS, USPS, DHL, into a decentralized and transparent system (Shah, 2017). *Microsoft*, *IBM*, and *Maersk* of Denmark are working in this field to digitize, manage, and track shipping transactions using blockchain technology.

Healthcare

There are two major applications of blockchain in healthcare. First, the supply, prescription, and usage of certain drugs could be recorded on the blockchain making these records transparent to physicians and regulators. Second, patients' medical history and treatment history could also be stored in blockchain making them available to healthcare providers and insurance companies, which can help avoid mistakes and reduce healthcare cost (Kuzmeskas, 2017). *Hashed Health*, based in Nashville, Tennessee, is a leading company focusing on applying blockchain and distributed ledger technologies in healthcare field.

Voting

Voting is the basic right of our citizens. For security and integrity reasons, voting has been done offline. As many other businesses and social activities are moving online, there is a demand to allow vote online. Blockchain technology can support this transition. Before the election, every eligible voter could receive a private key, which will be used to cast a vote on the election day. The vote is traceable, and the result is unchangeable and open to the public (Omohundro, 2014). *Follow My Vote* is a nonpartisan public corporation currently designing an online voting platform with blockchain technology. Their objective is to improve the integrity standards of voting systems worldwide.

FUTURE RESEARCH DIRECTIONS

Implication of Work

In the previous section, we discussed the potential applications of blockchain in various business fields. It is no doubt that blockchain is a disturbing technology and its impact on business and society has not been fully investigated.

First, blockchain applications can surely increase productivity, improve government efficiency, and reduce business operational cost. For example, the usage of blockchain on identity verification can reduce the workforce of security screenings at airports and government buildings. Second, like many new technologies, the usages of blockchain in certain areas will result in job loss. Keep in mind, technology is never the sole cause of business failure. Governments are held responsible to take actions to assist business transformation and make sure our society could smoothly adapt to changes.

Limitation of Work

As with any studies, there are some limitations to our work. First, blockchain is an emerging technology. It is not mature yet. Especially, we do not have long enough experience of using this technology. There could be other potential risks about this technology that have not been fully realized yet. Second, although there are many potential applications of blockchain, they are all in their early stages of development. The full adoption of blockchain technology may take years. Finally, the adoption of any technology, including blockchain, that might have impact on individuals and society, must be regulated. Currently, the legislature on blockchain technology is no doubt legged behind.

Future Work

The future research in this area can be described in the following directions. First, the impact of cryptocurrencies on our current financial systems and central banks should be studied. Second, the impact of blockchain technology on privacy protection should also be investigated. For example, if our computer that contains various private keys are hacked, our financial transactions, online identifications, ownership of properties could be exposed and stolen. Third, the social impact of blockchain should also be studied. Whenever new technologies are adopted, we need to make sure the technology-disadvantaged groups, such as elderly citizens, are still able to access all services using conventional mechanisms. For example, blockchain-based electronic ID should be a complement instead of a replacement of a hard copy ID; cryptocurrencies should never replace cash as the sole payment method in local stores, clinics, restaurants, and transportation services.

CONCLUSIONS

This paper described blockchain, its data structure and operation mechanism. It showed how transactions can be securely recorded in blockchain, making them traceable and transparent to the public. In addition, the development platform, the applications of blockchain in various fields are also described.

As with any emerging technologies, blockchain also has its drawbacks and barriers to industry. Ignoring its weakness may result in business losses, property damages, or operational failure. Below summarizes the risks of adopting blockchain technology.

- Blockchain transactions are recorded with public keys. To claim the ownership of a cryptocurrency, an identification, or a property, you must present your private key. If you lost your private key, you lost the ownership of the transaction. For identifications, such as passport, and some properties, such as a land, we might have other mechanisms to recover your ownership. However, for decentralized cryptocurrency, there is no way to recover a lost ownership.
- Blockchain records are closely related with hash functions. Loss of transaction records could result in failure of verifying subsequent transactions. This could happen if physical damage occurred to record storage due to natural disasters, war, or fire.
- Small scale blockchain records are more susceptible to hacker attacks. Although it is technically difficult for hackers to modify all the transaction records, it is still possible for hackers to modify these transactions if the data is small and stored centralized.
- Cost to maintain blockchain-based application could go higher as more and more transactions are recorded. Especially, some expired transactions cannot be removed. Instead they must be kept forever to verify some previous unexpired transactions. Therefore, record storage and record maintenance could be a headache for business in the long run.

Blockchain, as a disruptive technology, could have great impact on IT industry, business, and government organizations. Economically, blockchain is expected to revolutionize our business practices and reduce operating cost. Politically, blockchain could bring trust to society, democratize the global economy, and improve social relations. However, none of these goals could be achieved easily. It requires the collaborative work of governments, business, and other institutions. More and more leading companies in

various business and industry have strongly stated their positions in adopting blockchain technology. Their stance and white papers can be found in Section “Additional Readings.”

ACKNOWLEDGMENT

KEY TERMS AND DEFINITIONS

Binary Tree: A data structure in computer programs to store large amount of data. Compared with other data structures, binary tree provides the fastest access to a data item, in general.

Bitcoin: A decentralized digital currency system implemented with blockchain technology.

Blockchain: A distributed secured record-keeping system with a list structure.

Cryptographic Hash: A hash function used in computer security that takes input data and returns a fixed-size alphanumeric string.

Decentralized Network: A computer network that all nodes are equal and no single node controls the entire network.

List: A data structure used in computer programs to store data. List is composed of individual data blocks.

Public-Key Cryptography: A cryptographic technique that uses two asymmetric keys: a public key and a private key.

Cyber Crime Threats, Strategies to Overcome, and Future Trends in the Banking Industry

Atul Bamrara

Department of School Education, Government of Uttarakhand, India

INTRODUCTION

Cybercrime is a near and present threat for all organizations today. While primarily focused on the consumer and financial services industry for many years, cybercrime definitively made the shift into the enterprises. Cybercriminals are working everyday to create better technology that will lead to larger payoffs (Brown, 2015; Byrne et al., 2002; Broadhurst et al., 2014). They are switching their methods and hitting diversified targets to yield better information. As experienced by one organization: It took cybercriminals just four hours to overcome a countermeasure that had taken them four months to develop. Managing risk against the threat of cybercrime is certainly not easy an easy task (Taylor et al., 2014; Yuan et al., 2016). One of the most important lines of defense is intelligence and awareness of the potential risks and governments have been making great strides to embrace information sharing among competitors and partners, but most importantly, the general public (Bauer et al., 2017).

BACKGROUND

Strategies to Overcome Cyber Threats

When a bank's system is connected to the internet or intranet, an attack could originate anytime, anywhere. Some acceptable level of security must be established before business on the internet can be reliably conducted (Byrne et al., 2002; Bossler et al., 2012; Aboobucker et al., 2018). An attack could be any form like:

- The intruder may gain unauthorized access
- The intruder can destroy, corrupt or otherwise alter data
- The intruder does not gain access, but instead forges messages from user system
- The intruder does not gain access, but instead implements malicious procedures that cause the network to fail, reboot or hang

Modern security techniques have made cracking very difficult but not impossible. Furthermore, if the system is not configured properly or the updated patches are not installed then hackers may crack the system using security hole. A wide range of information regarding security hole and their fixes is freely available on the internet.

DOI: 10.4018/978-1-7998-3473-1.ch086

1. AUTHENTICATION TECHNIQUES

Authentication is the act of establishing genuineness or originality of a subject. It can be divided into many types depending on how it is performed. Authentication techniques evolved and got strengthened by continuous refinements so as to lessen attacks on private domains (Raza et al., 2011).

1.1 Single Factor Authentication

A well-known and trusted solution in the initial days of computerization was validation by a single attribute. It was effective in the days of localized processing and single user environments. But as networking and Internet based applications spread everywhere, and users were required to maintain passwords for many sites and different applications, they tended to use a single password for all applications on different websites (Fernando et al., nd; Shareef et al., 2018). There are several reported cases where attackers broke into low security websites and retrieved thousands of username/password pairs and directly try to use them by trial and error methods to enter high security e-commerce sites such as eBay with the intention of committing frauds.

1.2 Web Password Hashing

PwdHash is a browser extension that transparently converts a user's password into a domain-specific password (Simmons et al., 2006; Frankel et al., 2011). PwdHash automatically replaces the contents of these password fields with a one-way hash of the pair (password, domain-name). This makes the program on the website process only the domain-specific hash of the password, and not the password itself. A break-in at a low security website exposes password hashes rather than an actual password. Though this was a very effective technique, it required extensions to be added to the browsers. This feature if embedded into every browser will avoid the need to install any extensions.

1.3 Two Stage Authentication

All users cannot be expected to load extensions to their passwords as it requires some knowledge of processing and also as password-stealing attacks have become so common that the software industry observed that the two stage authentication may control the ID theft only to some extent (Subsorn et al., 2012). Businesses chose different methods for second stage authentication apart from passwords. The second input for authentication should preferably be dynamic and possessed by the authorized user. One-time passwords given through tokens, transaction numbers over mobile telephones, grids printed on the back of cards, dynamic digits from ATM card numbers, etc., all are entered as a second input for authentication and come in the increasing order of complexity and cost. Though these methods are loosely termed as second-factor authentication in reality these get used as knowledge based inputs and thus can be stolen or shared (Brown, 2015).

1.4 Multifactor Authentication

The FFIEC – Federal Financial Institutions Examination Council, issued supplemental guidance on authentication in August 2006, in which they clarified, “By definition true multifactor authentication

requires the use of solutions from two or more of the three categories of factors” (Shareef et al., 2018). Using multiple solutions of the same category, would not qualify as a multifactor authentication.

1.5 Multi Channel Authentication

One time transaction password sent by a bank to its customer on mobile telephone before the transaction is put through has become very popular. On the assumption that security over the Internet channel could be breached and mobile telephone channel is safer this additional stage was introduced (Raza et al., 2011). However, with convergence of different communication channels (Internet on mobile) and device convergence (iPod) implemented these solutions need to be continuously reviewed and more layers built in. Authentication process always uses authentication servers and the most common type of authentication servers include-

1.2.1 RADIUS (Remote Authentication Dial in User Service)

Remote Authentication Dial in User Service (RADIUS) is a networking protocol that provides centralized Authentication, Authorization, and Accounting (AAA) management for computers to connect and use a network service. RADIUS was developed by Livingston Enterprises, Inc., in 1991 as an access server authentication and accounting protocol and later brought into the Internet Engineering Task Force (IETF) standards (Simmons et al., 2006; Frankel et al., 2011). Because of the broad support and the ubiquitous nature of the RADIUS protocol, it is often used by ISPs and enterprises to manage access to the Internet or internal networks, wireless networks, and integrated e-mail services. These networks may incorporate modems, DSL, access points, VPNs, network ports, web servers etc. It is a client/server protocol that runs in the application layer, using UDP as transport. The Remote Access Server, the Virtual Private Network server, the Network switch with port-based authentication, and the Network Access Server (NAS), are all gateways that control access to the network, and all have a RADIUS client component that communicates with the RADIUS server. The RADIUS server is usually a background process running on a UNIX or Windows NT machine (Subsorn et al., 2012). RADIUS serves three functions-

1. To authenticate users or devices before granting them access to a network,
2. To authorize those users or devices for certain network services and
3. To account for usage of those services.

1.2.2 Kerberos

Kerberos is a computer network authentication protocol, which allows nodes communicating over a non-secure network to prove their identity to one another in a secure manner. Its designers aimed primarily at a client-server model, and it provides mutual authentication, both the user and the server verify each other's identity (Susborn et al., 2016). Kerberos protocol messages are protected against eavesdropping and replay attacks. Kerberos builds on symmetric key cryptography and requires a trusted third party, and optionally may use public-key cryptography by utilizing asymmetric key cryptography during certain phases of authentication. Kerberos uses as its basis the symmetric Needham-Schroeder protocol. It makes use of a trusted third party, termed a key distribution center (KDC), which consists of two logically separate parts: an Authentication Server (AS) and a Ticket Granting Server (TGS). Kerberos works on the basis of “tickets” which serve to prove the identity of users (Samaddar, 2009).

The KDC maintains a database of secret keys; each entity on the network — whether a client or a server — shares a secret key known only to itself and to the KDC. Knowledge of this key serves to prove an entity's identity. For communication between two entities, the KDC generates a session key which they can use to secure their interactions. The security of the protocol relies heavily on participants maintaining loosely synchronized time and on short-lived assertions of authenticity called Kerberos tickets. The client authenticates itself to the Authentication Server and receives a ticket (Yuan et al., 2016). It then contacts the Ticket Granting Server, and using the ticket it demonstrates its identity and asks for a service. If the client is eligible for the service, then the Ticket Granting Server sends another ticket to the client. The client then contacts the Service Server, and using this ticket it proves that it has been approved to receive the service. A simplified and more detailed description of the protocol follows. The following abbreviations are used:

- AS = Authentication Server
- SS = Service Server
- TGS = Ticket-Granting Server
- TGT = Ticket Granting Ticket

The client authenticates to the AS once using a long-term shared secret (e.g. a password) and receives a TGT from the AS. Later, when the client wants to contact some SS, it can (re)use this ticket to get additional tickets from TGS, for SS, without resorting to using the shared secret. These tickets can be used to prove authentication to SS.

1.2.3 TACACS+

TACACS+ protocol provides access control for routers, network access servers and other networked computing devices via one or more centralized servers (Meyers, 2014; Mbelli et al., 2016). TACACS+ provides separate authentication, authorization and accounting services. TACACS allows a client to accept a username and password and send a query to a TACACS authentication server, sometimes called a TACACS daemon or simply TACACSD. This server was normally a program running on a host. The host would determine whether to accept or deny the request and sent a response back. The TIP would then allow access or not, based upon the response. In this way, the process of making the decision is “opened up” and the algorithms and data used to make the decision are under the complete control of whoever is running the TACACS daemon. The extensions to the protocol provide for more types of authentication requests and more types of response codes than were in the original specification.

1.2.4 Lightweight Directory Access Protocol

The Lightweight Directory Access Protocol (LDAP) is a directory service protocol that runs on a layer above the TCP/IP stack. It provides a mechanism used to connect to, search, and modify Internet directories. The LDAP directory service is based on a client-server model (Mahmadi et al., 2016; Li et al., 2016). The function of LDAP is to enable access to an existing directory. The data model (data and namespace) of LDAP is similar to that of the X.500 OSI directory service, but with lower resource requirements. The associated LDAP API simplifies writing Internet directory service applications

1.3 Cryptography

Cryptography is the science of writing in secret code and is an ancient art; the first documented use of cryptography in writing dates back to circa 1900 B.C. when an Egyptian scribe used non-standard hieroglyphs in an inscription. Some experts argue that cryptography appeared spontaneously sometime after writing was invented, with applications ranging from diplomatic missives to war-time battle plans. It is no surprise, then, that new forms of cryptography came soon after the widespread development of computer communications (Kessler, 2011). In data and telecommunications, cryptography is necessary when communicating over any insecure medium, which includes just about any network, particularly the Internet. A variety of cryptographic methods may include Secret Key Cryptography, Public Key Cryptography or Hash Functions.

1.4 Database Security

Data base Management Systems are increasingly being used to store information about all aspects of an enterprise (Mahmadi et al., 2016; Mbelli et al., 2016). The data stored in a DBMS is often vital to the business interests of the organization and is regarded as a corporate asset. In addition to protecting the intrinsic value of the data, bank must consider ways to ensure privacy and to control access to data that must not be revealed to certain group of users for various reasons (Tham, 2017). A database of the bank contains a great deal of information and usually has several groups of users. Most users need to access only a small part of the database to carry out their tasks. Allowing users unrestricted access to all the data can be undesirable and a DBMS should provide mechanisms to control access to data. A DBMS uses two main approaches to access control.

1.4.1 Discretionary Access Control

Discretionary access control is the principle of restricting access to objects based on the identity of the subject (the user or the group to which the user belongs). Discretionary access control is implemented using access control lists. A resource profile contains an access control list that identifies the users who can access the resource and the authority (such as read or update) the user is allowed in referencing the resource. The security administrator defines a profile for each object (a resource or group of resources), and updates the access control list for the profile (IEEE, 2011). This type of control is discretionary in the sense that subjects can manipulate it, because the owner of a resource, in addition to the security administrator, can identify who can access the resource and with what authority.

1.4.2 Mandatory Access Control

Mandatory Access Control (MAC) ensures that the enforcement of organizational security policy does not rely on voluntary web application user compliance (IEEE, 2011). MAC secures information by assigning sensitivity labels on information and comparing this to the level of sensitivity a user is operating at. In general, MAC access control mechanisms are more secure than DAC yet have tradeoffs in performance and convenience to users.

MAC mechanisms assign a security level to all information, assign a security clearance to each user, and ensure that all users only have access to that data for which they have a clearance (IEEE, 2011). MAC is usually appropriate for extremely secure systems including multilevel secure military applica-

tions or mission critical data applications. A MAC access control model often exhibits one or more of the following attributes:

- All users can read from a lower classification than the one they are granted (A “secret” user can read an unclassified document).
- All users are given read/write access to objects only of the same classification (a “secret” user can only read/write to a secret document).
- Only administrators, not data owners, make changes to a resource’s security label.
- All users can write to a higher classification (A “secret” user can post information to a Top Secret resource).
- All data is assigned security level that reflects its relative sensitivity, confidentiality, and protection value.
- Access is authorized or restricted to objects based on the security characteristics of the HTTP client (e.g. SSL bit length, version information, originating IP address or domain, etc.)
- Access is authorized or restricted to objects based on the time of day depending on the labeling on the resource and the user’s credentials (driven by policy).

1.5 Network Security

We say a network is secure if the connection obeys CIA property. To provide security in a network many security protocols are being designed by Internet Authority time to time. Web came into being in early 90s; researchers started thinking about to provide security to web and web transaction (Simmons et al., 2006).

1.5.1 IPSEC

Internet Protocol Security is a protocol suite for securing Internet Protocol (IP) communications by authenticating and encrypting each IP packet of a communication session (Frankel et al., 2011). It includes protocols for establishing mutual authentication between agents at the beginning of the session and negotiation of cryptographic keys to be used during the session. It is an end-to-end security scheme operating in the Internet Layer of the Internet Protocol Suite (Zhang et al., 2015). It can be used in protecting data flows between a pair of hosts (host-to-host), between a pair of security gateways (network-to-network), or between a security gateway and a host (network-to-host).

1.5.2 SSL

The Secure Sockets Layer (SSL) protocol was developed by Netscape Communications to provide application-independent secure communication over the Internet for protocols such as the Hypertext Transfer Protocol (HTTP). SSL employs RSA and X.509 certificates during an initial handshake used to authenticate the server (client authentication is optional). The client and server then agree upon an encryption scheme; SSL v2 supports RC2 and RC4 with 40-bit keys, while SSL v3 adds support for DES, RC4 with a 128-bit key and 3DES with a 168-bit key, all along with either MD5 or SHA-1 message hashes. SSL v3 is the commonly supported version on servers today, although some implementations of SSL v2 will still be found; both are supported by most common browsers

1.5.3 DNSSEC (DNS Security Extension)

DNSSEC was designed to protect the Internet from certain attacks, such as DNS cache poisoning. It is a set of extensions to DNS, which provide: a) origin authentication of DNS data, b) data integrity, and c) authenticated denial of existence (Meyers, 2004).

These mechanisms require changes to the . DNSSEC adds four new resource record types: Resource Record Signature (RRSIG), DNS Public Key (DNSKEY), Delegation Signer (DS), and Next Secure (NSEC).

1.5.4 WEP

Wired Equivalent Privacy (WEP) is the encryption algorithm built into the 802.11 (Wi-Fi) standard. WEP encryption uses the RC4 stream cipher with 40 or 104 bit keys and a 24 bit initialization vector. Most 802.11 devices allow WEP keys to be entered using an ASCII passphrase or in hexadecimal format. The conversion between these two formats is an industry standard which is shared by almost all vendors of 802.11 equipment.

1.5.5 WPA

Wi-Fi Protected Access (WPA) and Wi-Fi Protected Access II (WPA2) are two security protocols and security certification programs developed by the Wi-Fi Alliance to secure wireless computer networks (Subsorn et al., 2012). The Alliance defined these in response to serious weaknesses researchers had found in the previous system, WEP (Wired Equivalent Privacy). The WPA protocol implements the majority of the IEEE 802.11i standard. The Wi-Fi Alliance intended WPA as an intermediate measure to take the place of WEP pending the preparation of 802.11i. Specifically, the Temporal Key Integrity Protocol (TKIP), was brought into WPA. TKIP encryption replaces WEP's small 40-bit encryption key that must be manually entered on wireless access points and devices and does not change. TKIP is a 128-bit per-packet key, meaning that it dynamically generates a new key for each packet and thus prevents collisions.

1.5.6 RSN (ROBUST SECURITY NETWORK)

The RSN is a security network that only allows the creation of robust security network associations (RSNAs), which are a type of association used by a pair of stations (STAs) if the procedure to establish authentication or association between them includes the 4-Way Handshake. It also provides two RSNA data confidentiality and integrity protocols, TKIP and CCMP, with implementation of CCMP being mandatory.

1.6 Security Policy

Various information security policies have been developed by the organizations to overcome the attack of cyber threats. Information security means protection of the banks' data, applications, networks and computer systems from unauthorized access, alteration or destruction (Baeur et al., 2017; Broadhurst et al., 2014). The purpose of information security is-

- To establish an organization wide approach to information security.

- To prescribe mechanisms that help identify and prevent the compromise of information security and the misuse of banks' data, applications, networks and computer resources.
- To define mechanisms that protect the reputation of the bank and allow the bank to satisfy its legal and ethical responsibilities with regard to its networks' and computer resources' connectivity to worldwide networks.
- To prescribe an effective mechanism to external complaints and queries about real or perceived non compliance with this policy.

The bank uses a layered approach of overlapping controls, monitoring and authentication to ensure overall security.

1.6.1 Data Classification Policy

It is essential that the entire bank's data should be protected. These are however gradations that require different levels of security (Samaddar, 2009). All data should be reviewed on periodic basis and classified according to its use, sensitivity and importance. **High Risk** information assets for which there are legal requirements for preventing disclosure of financial penalties for disclosure. Data covered by federal and state legislation such as FERPA, HIPAA or the data protection Act are in this class. Payroll, personnel and financial information are also in this class because of privacy requirements. This policy recognizes that other data may need to be treated as high risk because it would cause severe damage to the bank if modified or disclosed. **Confidential** data that would not expose the bank to loss if disclosed, but that the data owner feels should be protected to prevent unauthorized disclosure. It is the data owner's responsibility to implement the necessary security requirements. **Public** information that be freely disseminated should be categorized and protected according to the requirements set for each classification. The data classification and its corresponding level of protection should be consistent when the data is replicated and as it flows through the banking environment.

1.6.2 Access Control Policy

The branches and top level management must have a standard policy that applies to user access rights. This will suffice for most instances (IEEE, 2011). Data owners or custodians may enact more restrictive policy for end user access to their data. There is a delicate balance between protecting the data and permitting access to those who need to use the data for authorized purposes. This balance should be recognized.

1.6.3 Virus Prevention Policy

The willful introduction of computer viruses or disruptive/ destructive program into the bank is prohibited and violators may be subject to prosecution. All servers and workstations that connect to the network and that are vulnerable to virus or worm attack must be protected with an approved, licensed antivirus software product that is kept updated according to the vendor's recommendations. Headers of all incoming data including electronic mail must be scanned for viruses by the email server where such products exist and are financially feasible to implement. Outgoing e-mail should be scanned where such capabilities exist (Samaddar, 2009; Mbelli et al., 2016).

1.6.4 Intrusion Detection Policy

Operating system and application software logging processes must be enabled on all host and server systems. Where possible, alarm and alert functions as well as logging and monitoring systems must be enabled. Server, firewall and critical system logs should be reviewed frequently. Where possible, automated review should be enabled and alerts should be transmitted to the administrators when serious security intrusion is detected.

1.6.5 System Security Policy

System integrity checks of host and server systems housing high risk data should be performed. All the systems connected to the internet must be updated with security patches.

1.6.6 Acceptable Use Policy

Bank's computer resources must be used in a manner that complies with bank's policies, state and federal laws and regulations. Use of computing and networking infrastructure must be limited in both time and resources and must not interface in any way with bank's functions or the employee's duties.

1.6.7 Government Policy

India's business, data and knowledge process outsourcing industries have been growing significantly in the last few years. However, various incidents of data theft and misuse of public and private information have raised concerns about outsourcing to India. Unlike the US or the European Union, India does not have a data protection law. Privacy rights are enforced under the Indian Constitution and the Information Technology Act 2000, whereas Indian Contract Act 1872, Copyright Act 1957 and the Indian Penal Code 1860 protect property rights.

Future Research Directions

The banking industry is undergoing an incredible amount of technological change as these firms release new and exciting features in the hopes of gaining a competitive edge in an ever-changing market. The banking industry experienced a critical change when clients were introduced to the concept of mobile banking. Millions of customers use their cell-phones every day to conduct important transactions, and this number is only increasing. But as open banking continues to accelerate, countless new threats are presented. Although this degree of innovation has an overall positive effect on the industry, it poses many new issues that tech experts will have to combat very quickly. Whether that be the use of third-party apps, unusual consumer behavior, or unsecured wifi networks, it is clear that these banks are constantly at risk. The security of digital communication and transactions is of critical importance and the management of risk to such information systems is considered fundamental to effective cyber security. In the context of such challenges, the need for effective cryptographic systems and the complex mathematics and logic that underpin them have become ever more important. The future of information security will be built around four pillars, namely, Blockchain technologies, artificial intelligence, crowd sourcing, and global cyber-security cooperation (Guo et al., 2016). Many organizations will utilize two or more

of those pillars. An enterprise may combine artificial intelligence to detect security vulnerabilities and crowd testing to confirm the detected vulnerabilities.

CONCLUSION

In the past, banks have been one of the primary investors in security, and this trend is likely to continue as the industry begins to explore this new landscape. As open banking grows, banks will hold data that is more and more interconnected, and they simply cannot afford to take risks. One leak could proceed to cause a chain reaction throughout the entire industry. The larger the problem gets, the harder it will be to control.

Combating these threats certainly will not be easy, but is possible if financial firms are willing to create an adaptive and flexible strategy of detecting, defending, and counter-attacking hackers. One of the many lessons learned during the last few years was that these banks need to find a better way to deal with risk. Although several of these companies are outsourcing their security services in order to ensure comprehensive coverage, the companies themselves need to mitigate these risks by developing software that is less prone to attacks in the first place. By beefing up their own cyber-security, they are not only investing in the future of banking, but also doing what they can to avoid another crisis.

KEY TERMS AND DEFINITIONS

Brute Force: Brute force attacks use a trial and error approach to acquire information or rights. Instead of intellectual strategies, the attacker uses an exhaustive search technique.

Buffer Overflow: Buffer overflow occurs when a temporary storage area is filled with more data than it was designed to hold. The extraneous data can overflow into adjacent storage causing software failure or, if the data is carefully designed to behave as instructions that trigger unwanted actions.

Crafted Input: Crafted input is carefully designed to disrupt the normal execution of a system. For example, a JPG image can be designed to put the image decoder into an infinite loop.

Cross-Site Scripting: Cross-site scripting is another means of attacking a web server that provides dynamic pages to clients. Scripts embedded in HTML requests can trick an unsuspecting surfer into executing the scripts. These attacks normally are used for information acquisition leading to connection hijacking.

Direct Request to a Resource: Direct request to a resource accesses sensitive data through valid means. The access is allowed because of a limitation in the software or misconfiguration of the software and not because of cleverness on the part of the attacker.

Directory Traversal: Directory traversal attacks commonly target web servers that have the ability to present dynamic pages. Instead of a simple page name, a relative path name is requested which could lead to the acquisition of sensitive data.

Format String: Format string attacks take advantage of software that accepts unfiltered user input. If the input is passed to a formatting function such as `printf()` in C, then tokens such as `%s`, `%x`, and `%n` can be used to obtain information stored in the runtime stack.

Metacharacters: Metacharacters (such as `?` or `*`) are not properly checked before being passed to the underlying system in a system vulnerable to a metacharacter attack. These characters, interpreted by the underlying system, can be used to execute arbitrary commands.

PHP Remote File Inclusion: PHP remote file inclusion allows a remote user to upload to and possibly execute an arbitrary file on a web server. In the general case, a carefully constructed value is passed to the server which contains the name of the remote file to access.

Spoofing: Spoofing is an identity deception used to gain access to restricted resources. Example items to spoof are IP addresses, port numbers and usernames. Secure Shell programs are not even immune to spoofing.

SQL Injection: SQL injection vulnerabilities are exploited by placing database queries in the form of SQL statements into web server requests. The result is the execution of the SQL statement at the server and the return of the query results to the client.

Web Cache Poisoning: Web cache poisoning is accomplished by altering the contents of a web server's cache of pages. Instead of returning the requested page, the modified version in the cache is returned which may contain redirections or arbitrary scripts.

Cybersecurity Risks in Romanian Companies

INTRODUCTION

Risk management process is proving to be an essential factor for the development and stability of an organization, it is the basis for developing a sustainable strategy for achieving organizational objectives and the basis for planning and decision making (Singh & Fhom, 2017).

At the same time, sophisticated attacks are expected directed to the staff users of the communication and information systems, such as social engineering attacks, correlation between office, ISP, and home computers or mobile device attacks. State-sponsored cyber terrorism is of great concern for state authorities, as this new form of terrorism is cheap and ready available to practically everyone, on each side of the world and it can lead to major disruptions in modern societies. The uncertainty may take the form of either threats or opportunities. Thereby, each manager must handle threats, because otherwise the organization's objectives cannot be met and capitalize the opportunities to the benefit of the organization, proving efficiency (McQuade, 2006; He, Chen, Chan, & Bu, 2012).

Among the most important factors of disruptive impact on the activities of an organization, risk factors are, by far the leading place.

Risk, as defined in the western socio-economic and military environments, can occur anywhere: within the organization, structure, and decision-making process, the relationship with the external environment, the management and policies of the organization (Ruževičius & Gedminaitė, 2007).

In order to identify, analyze and organize organizational risk assessment activities to reiterate the importance of the organizational concepts of systems theory perspective (Hjortdal, 2011; Chen, Ge, & Xie, 2015).

Risk treatment is the second important step in risk management organizational stage where management organization has the key role in the adoption of the most appropriate decision in terms of the balance between the need to fulfill the performance indicators proposed and costs (Hadžiosmanović, Bolzoni, & Hartel, 2012).

Stage security risk treatment is based entirely on the results of the risk analysis phase, the risks have been identified and ranked in terms of the impact that their implementation can have on the organiza-

tion's mission. This is why, security mechanisms have to be properly designed and commensurate with the specific threats for the specific types of information (Tropina & Callanan, 2015).

Choosing an effective strategy development organization should consider the risks and vulnerabilities exposed to treatment solutions adapted to the needs of each organization's risk and reduce costs, both short and long term. Meanwhile, the adoption of certain measures that contribute to risk management is conditioned by the nature of the organization and the costs incurred for these measures.

As such, also in Romanian companies, concern continues to diminish the effect of unwanted influence involves a compulsory, dedication of resources which, if prolonged neglect can radically affect the overall level of resources of an organization and therefore, the quality of its task.

In order to achieve this aim, the chapter analyzes a number of problems of research. Firstly, this study explores the Romanian organizations' attitude towards information technology security. Secondly, the protection of this infrastructure represents a major concern of authorities all around the world. Information security has become a top of mind issue for the public, media and government. And last but not least, it investigates the necessity to develop a structured process of information security risk within the organization. It must be borne in mind that, regardless of the type of organization, the field of activity or form of organization, there is uncertainty both in organization and in the environment in which it operates. Given that uncertainty is a fact of life, then the uncertainty response should become a permanent managerial concern.

However, collective efforts are necessary, at both national authorities' level and managers of public and private organizations in order to ensure a safe and trusted cyber space. The awareness of potential threats and vulnerabilities is thus vital, as well as preoccupation towards cooperation in countering them by well-established rules and mechanisms created at national and organizational level.

BACKGROUND
